DR. KIMBALL, of Lowell, said that Dr. Homans's operations stand better than the average in this line of surgery. In 1863 Koerberle, in a pamphlet entitled "Extirpation of the uterus by the supra-pubic method," gives a list of 51 cases. In 14 of these there was a wrong diagnosis; only nine of them recovered, and five died. He gives 20 pediculated cases, of which eight recovered and 12 died. In 1864 Catemault gave a record of 76 cases, with 53 deaths and 23 recoveries. In 1869 Pean gave 41 cases, with 30 deaths and 11 recoveries, and Pozzi 119 cases, with 77 deaths and 12 recoveries. Dr. Kimball himself had operated upon 12 cases, six of which recovered and six died. The 18 cases he had to add to the 119 already recorded by Pozzi are as follows:—

(1) Dr. Kimball, of Lowell. Solid fibroid, mistaken diagnosis; died on the eleventh day.

(2) Dr. Kimball. Solid fibroid; 30 pounds; cured.

(3) Dr. Kimball. Fibro-cystic tumor; died at the end of the seventh week from septicæmia.

(4) Dr. Kimball. Fibro-cystic; cured.

(5) Dr. Kimball. Fibro-cystic; died from septicæmia the third week.

(6) Dr. Kimball. Pediculated fibroid; 16 pounds; cured.

(7) Dr. Kimball. Solid fibroid; twenty pounds; died from shock on the fourth day.

(8) Dr. Kimball. Fibro-cystic; cured.

(9) Dr. Kimball. Fibro-cystic; cured.

(10) Dr. Kimball. Solid fibroid; 20 pounds; died the fourth day from peritonitis and septicæmia.

(11) Dr. Kimball. Solid fibroid; 12 pounds; died on the fifth day from peritonitis.

(12) Case in Vermont. Cured. Some months later died of brain disease.

(13) Dr. Thomas, of New York. Weight fifty pounds; died from hemorrhage the third day.

(14) Dr. W. H. Byford, of Chicago. Fibro-cystic tumor; died from shock.

(15) Dr. J. R. Chadwick, of Boston. Fibro-cystic tumor; died the eighth day from tetanus.

(16) Dr. Potter, Providence, R. I. Solid fibroid; cured.

(17) Dr. T. A. Emmet, of New York. Died from shock.

(18) Samaritan Hospital, London. Communicated by Dr. Keith, of Edinburgh; cured.

Such was the record eight years ago. Of course, it has been greatly enlarged since that time, and results correspondingly improved.

Regarding the question whether the pedicle should be kept outside or dropped back, Dr. Kimball said he generally prefers to keep it outside. The practice of Pean has been to draw the pedicle outside. His mode of procedure at the time Dr. Kimball saw him operate was as follows: He first brought the tumor to view by an incision five or six inches in length; then, seizing it with a vulsellum, he brought it firmly forward into the incision, thus preventing the escape of intestines through the opening. He next transfixed it with two long needles crossing each other at right angles, and applied behind them a ligature of annealed iron wire, drawn sufficiently tight by an *écraseur* to cut off the circulation; then, after cutting away so much of the tumor as had been drawn outside the incision, he proceeded to repeat the same process, namely, bringing forward the remaining portion of the tumor and cutting it away, slice after slice, till he finally came to the neck, or pedicle, which, after carefully ligating it with wire, he brought forward and secured at the lower end of the incision by a long, stout needle passed transversely through its centre.

The tumor shown by Dr. Homans weighs thirty pounds. Dr. Kimball spoke of removing one of the same weight from a lady living in Longmeadow, this State. In that case he transfixed the pedicle and tied the two halves with silk, and around the whole passed a ligature of annealed wire, and brought the pedicle up to the lips of the wound, the wire ligatures being kept outside, while those of silk were passed down and out by the vagina. The recovery was slow, and the ligatures were a very long time coming away.

The first case of uterine tumor he ever had he

diagnosed as ovarian. The patient died two weeks after the operation. In his next case he took out the uterus and both ovaries. The woman recovered. Dr. Kimball said that the most remarkable case that he had had anything to do with, as showing the possibilities of this kind of surgery, was that of a woman from Providence. She had a large fibroid tumor, which was pressed so firmly into the vagina that the os could not be felt, a case such as he considered ought not to be touched, but upon telling the patient so she became very indignant. Two weeks after returning home she induced her family physician to operate. The tumor, which was extensively adherent to the adjacent parts, was transfixed and tied in sections. In the course of the operation the bladder was cut into to the extent of one and one-half inches, and so was the intestine to the same extent; both of these openings were closed with silver sutures. This patient finally recovered, and the sutures came out one after another in every direction, some of them through the bladder and others through the wound. The woman is now perfectly well.

One of Dr. Kimball's rules is not to remove a uterine fibroid when it is crowded down into and involves the vagina. It is oftentimes very difficult to decide what to do in these cases, but, as a rule, he refuses to operate, for they are always exceedingly unpromising. He had a case of this kind in Vermont. The operation was performed according to Pean's method, that is, of slicing it off, piece after piece, and finally embracing the pedicle in a ligature of annealed wire, drawn tight by an *écraseur*, which also served by its connection with the *écraseur* to keep the pedicle outside. The actual cavity was used at first as a guard against secondary hemorrhage; afterward, as there was considerable oozing of blood, persulphate of iron was used very freely. The bleeding was finally controlled by further tightening the ligature with the *écraseur*. In this case the intestines were not exposed. The wound healed up slowly, but perfectly, and the patient recovered from the operation, but two months later died from disease of the brain.

He does not believe it a wise plan to operate unless the patient can be completely under the surgeon's control. He uses the antiseptic precautions from first to last. Dr. Keith is understood to have had already eighteen or more cases, with only two deaths. He has certainly had wonderful success. He takes entire care of his cases, which are usually in a private establishment only two or three doors from his own house. Dr. Kimball never operates on a woman merely because she has a tumor and desires to have it removed, because frequently these tumors can be carried for a lifetime with no very serious inconvenience. One of Dr. Kimball's first operations for the removal of a fibroid tumor occurred in Connecticut. He had been sent for to remove an ovarian tumor. He found, instead of an ovarian, a fibroid tumor of the uterus. The patient was suffering from excessive uterine hemorrhages, was anemic to the last degree, and so feeble as to be unable to turn herself in bed. Her menstruation was regular, and she was within three days of the next period, which she felt sure would prove fatal. As a last resort, it was proposed to

remove the uterus. After frankly stating to the parties interested the great risk attending such a procedure, the proposition was unhesitatingly accepted, and the organ removed. The patient made a slow but perfect recovery. Dr. Kimball saw her several years after the operation, enjoying excellent health. She has gained sixty pounds in weight since the operation. This, he believed, was the first operation of the kind ever deliberately proposed and successfully executed in connection with a correct diagnosis.

The operation was severely criticized at the time by a distinguished professor in one of our New England medical colleges, and his criticisms were repeated from time to time, until it was finally announced to his class that the patient was in a fair way of recovery. In this case both ovaries were removed with the tumor.

Dr. MARCY was reminded, by Dr. Kimball's report, of the first case of hysterectomy he had ever seen. It was ten or more years ago. He had assisted Dr. Kimball in the removal of a large ovarian cyst. There was an interstitial fibroid, the size of a goose's egg, in the fundus. The wire loop of the *écraseur* was applied to the cervix, and the portion above removed with scissors. Hemorrhage was controlled by the retention of the *écraseur* in the wound. Tetanus supervened the third day. The autopsy showed the complication of septic peritonitis. Dr. Marcy had performed hysterectomy three times at his private hospital in Cambridge. The first time for a multiple myoma, and he removed uterus and ovaries. The patient made an easy and rapid recovery. The second was for cancer of the fundus, in which operation he was assisted by Dr. Kimball. The patient died the fifth day of septic nephritis. The autopsy showed a clean, healthy peritoneal cavity, but in the stump of the cervix there was a small abscess. The third case was the removal of a large fibroid, about eight pounds in weight. The patient was exceedingly anemic from severe and repeated hemorrhages. Death occurred on the fourth day, preceded by continued vomiting, prior to which everything had appeared to progress favorably. The autopsy revealed no local cause of death. The stump was large, but no hemorrhage had occurred, and repair processes had already commenced.

Dr. Marcy entered at some length into the discussion of the treatment of the pedicle. The advantages of the intra-peritoneal method are obvious. Granted, its security from hemorrhage, with an aseptic condition of the peritoneal cavity, the complete closure of the abdominal wound, with proper dressings, puts out of account the greatest danger of all, septic poisoning. The extra-peritoneal method of treatment of the stump had the advantage of keeping the wounded surfaces, liable to bleed, under easy observation and control. However carefully dressed, the wound is one kept aseptic with much difficulty, and danger usually supervenes from this cause.

It had occurred to Dr. Marcy some years since that the method used by dentists in protecting a carious tooth from contamination from the fluids of the mouth might be used with advantage in the protection of the abdominal cavity and viscera in the

removal of uterine and other tumors. This is effected as follows: A sheet of pure gum rubber, medium bandage thickness, about one yard square, has a circular opening in the centre of about three inches in diameter. This is reinforced by a ring of pure rubber about one fourth of an inch in diameter, which not only greatly strengthens the opening, rendering it less likely to tear, but after it has been crowded quite down to the base of the tumor, makes a most efficient point of support for the elastic ligature. This pure rubber cord is applied in one or more turns, as may be sufficient to control hemorrhage about the base, and the tumor is removed. The stump is cut in a double flap, and the edges approximated so that the peritoneal surfaces may be brought together, and it is carefully closed by the over-and-over continuous suture of animal tendon. First, however, the base of the stump just above the elastic ligature is sewed through and through by a continuous suture, shoemaker's stitch. This is effected by a strong needle set in a firm handle, with the eye near the point. The needle has a rounded, not a cutting, point. Threaded with a strong kangaroo, chromicized tendon, the stump is transfixed, unthreaded, and the opposite end of the tendon threaded and withdrawn. In this manner stitch after stitch, in as fine subdivision as may be judged wise, is repeated until the entire stump is sewed through. Treated in this manner it is believed necrosis of the enclosed portion does not take place, the tissues of the stump being only in a moderate degree devitalized. If true, it is a manifest gain over the various methods of ligature, cauterization, etc., now more generally in use, since necrosed tissue, even if aseptic, is, like any foreign body, to be avoided if possible. Dr. Marcy had used this method of procedure in a considerable variety of operations for a number of years with the greatest of satisfaction. He first described it at the International Medical Congress in London in 1880, and afterward at the American Medical Association at St. Paul, and it is published at length in the *Transactions*.

If trustworthy, the advantages are certainly marked. It renders the operation, usually dreaded because of severe hemorrhage, nearly bloodless. It protects the abdominal cavity from contamination and manipulative irritation. With proper precaution the operation is not likely to be followed by septic poisoning. The abdominal wound is closed, and resultant treatment thereby is greatly simplified.

DR. J. R. CHADWICK said that his experience had been even less fortunate than that of Dr. Marcy, as he had had but three cases, all of which were fatal. The first<sup>1</sup> was in 1875, when he had removed by abdominal section a fibroid tumor occupying the body of the womb, and weighing four pounds; the pedicle, which consisted of the cervix uteri and broad ligaments, was secured externally by the clamp. The woman escaped all the ordinary risks, and was convalescent, when tetanus set in on the seventh day, and she died on the eighth. The autopsy showed commencing cicatrization of the wound, and freedom from peritonitis, septicaemia, and other lesions.

The second case was in a French Canadian, who came to his private hospital in 1880 for the removal of an abdominal tumor, supposed to be ovarian. The uterus was imbedded in the mass, weighing about twenty pounds, so that it was removed down to the vaginal insertion. The pedicle, consisting of the cervix and broad ligament, was very large, and was tied by many stout sutures, and cauterized by perchloride of iron. She died of secondary hemorrhage a few hours after the operation. A cystic degeneration of the right kidney was observed at the time of the operation.

The third case occurred last winter. Dr. Chadwick tapped the woman at his private hospital, and drew off thirty pounds of ascitic fluid, when a hard, rounded tumor was discovered filling the lower abdomen, and continuous with the uterine body. Two months later she returned with the abdomen more distended than before, and demanded a radical operation. Although Dr. Chadwick gave a poor prognosis, as he suspected, from the rapidity of the tumor's development and the presence of the ascites, that the growth was malignant, he drew off fifty pounds of ascitic fluid, and three days later (June 13, 1884) operated. The tumor involved the whole body of the uterus. At its upper end entered a large bundle of enormous blood-vessels, the origin of which was uncertain, perhaps from the omentum. These were tied and cut. The pedicle was the cervix uteri enlarged to the size of one's wrist; this was transfixed and tied with stout cord. After the tumor was cut away the pedicle had to be transfixed many times before all hemorrhage was arrested. The patient died of shock thirty hours after the operation. The tumor weighed four pounds; its structure was at first pronounced by Dr. W. F. Whitney to be sarcoma, but he was subsequently inclined to look upon it rather as an ordinary fibro-myoma than as a sarcoma. From this opinion its clinical history and gross appearances oblige Dr. Chadwick to differ. He believes that it was sarcoma.

A few operators have had exceptionally good results after this operation, but in general the prognosis is still much less favorable than in ovariectomy. We are consequently led to seek relief to our patients by such operations as Hegar's—the removal of the ovaries, and Tait's—the removal of the ovaries and Fallopian tubes. In both of these operations, especially in the latter, the greater part of the broad ligaments and their vessels is tied. He has long entertained the belief that we might ultimately find that merely tying the ligaments, and thus cutting off most of the blood-supply to the tumor and womb, would prove to be the essential step of these operations, and that all cutting might be dispensed with. To this opinion he has been led by an attempt that he made several years ago to extirpate, by Freund's method, a universally cancerous womb. He was compelled, by various complications, to desist from the extirpation, but before closing the abdomen he tied both broad ligaments. The woman survived the operation for a year, and he was gratified to note that the severe hemorrhages to which she had been subject did not recur. Had the disease been non-malignant he thinks it might have been arrested. He has had no opportunity to

<sup>1</sup> Boston Medical and Surgical Journal, November 4, 1875.

test his theory. If it should prove true, it seems as though it might be feasible to encircle the vessels in the broad ligament by a ligature, with the aid of an aneurism needle introduced through the walls of the vagina, and thus the danger of opening the abdominal cavity would be avoided.

Dr. Elliot is probably correct in his belief that Tait's operation is most successful with small tumors, but in view of the slow growth of most fibroid tumors and the little inconvenience that they cause the patient, Dr. Chadwick is strongly opposed to subjecting patients to the danger, even of that operation, when the tumor is still small. He has been surprised to find in how many of these growths he has been unable to detect any enlargement, even when followed for years.

Dr. KIMBALL remarked that we should consider if there was any method other than laparotomy that could be resorted to with a fair degree of success to stop the growth or lessen the size of fibroids. For this purpose Dr. Atlee, of Philadelphia, tried the muriate of ammonia, given in doses of ten grains three times a day, continuing it in some cases for months and even for years, and claimed for it many cures. Dr. Kimball had not had satisfactory results from its use. In one case, however, where he used it the woman was perfectly well in the course of a single year. Another way by which these growths have sometimes been arrested is by an incision through the parietes covering the tumor, thereby creating an impression, either by shock or otherwise, which is followed by a suspension of its further development. He mentioned a case which was supposed to be ovarian, but upon cutting down to the tumor a uterine fibroid was brought to view. The operation was discontinued. Years afterward the attending physician informed Dr. Kimball that the tumor had ceased to grow after the operation. Still another case of fibroid which had been diagnosed as ovarian was cut down upon and the tumor exposed. The wound was closed at once, peritonitis supervened, the woman recovered, and the tumor finally disappeared entirely. Dr. Green, of Portland, made a similar mistake in diagnosis. The tumor was exposed by an incision through the parietes, and the woman got well, the tumor disappearing soon after. Another peculiar case of fibroid was one that Dr. Kimball cut down upon, but the tumor was found to be so firmly adherent that it could not be dislodged. The wound was closed. It finally healed, but not till she had suffered severely from peritonitis. The justification for the operation was that the woman had had several frightfully severe hemorrhages. After the operation they ceased entirely, and she continued in comfortable health for more than twenty years, and finally died about one year ago from some other disease.

Dr. Kimball said that he has tried electrolysis, and sometimes with good results. Formerly he punctured the tumor through the abdominal wall, introducing the electrodes at a distance of about three inches from each other. Now he introduces one electrode into the uterus, and places the other outside, over the abdomen. The results have been so directly connected with this operation that he believes that great benefit is oftentimes derived from it. He mentioned a case in particular, where

he passed a galvanic current into the tumor through the abdominal wall and the tumor disappeared entirely within a year. Another case got entirely well after submitting to the electro-galvanic treatment. More than a year after the operation he examined the woman and found no trace of the tumor. Many other instances might be given when the passing a galvanic current through a fibroid tumor has been followed by equally satisfactory results.

Dr. HOMANS said that Dr. Keith has just reported eighteen cases of hysterectomy, with three deaths, in addition to the thirty-five cases he reported about two years ago. Dr. Keith owes his success to his careful, patient operating, and to the fact that he blames himself if his patients die, and not the climate, or the spray, or the surroundings. Dr. Keith uses the actual cautery in securing the ovarian pedicle, and does not use the ligature, and Dr. Homans believes that Dr. Keith expects much from the cautery in the treatment of uterine tumors by hysterectomy.

#### NEW YORK COUNTY MEDICAL ASSOCIATION.

STATED meeting, March 16, 1885.

##### ÆTIOLOGY OF STILL-BIRTHS.

Dr. JOHN SHREADY read a paper on the ætiology of still-births, in which he said that statistical tables, which varied greatly in the summing up of the average mortality, did not throw much light on the true causes of death. Besides, for prudential reasons in the suppression of crime, health boards and bureaus of registry in large cities required the burial of the fetus of any age, and thus the accounting certificate, classifying the return as a still-birth, necessarily swelled the death-rate more than the facts warranted. Again, no statistics could discriminate between the conservative and the reckless practitioner, much less determine how many lives have been saved by the obstetric art. Who could, in his own judgment, he asked, draw the line, so far as any of these reports were concerned, between a proper waiting upon nature and the resort to more decided measures? Still, the fact could not be gained that still-births are uncomfortably frequent, nor in our calculations with wide columns of figures could we hope to materially reduce the number.

In the front rank of devitalizing agencies, of course, stood syphilis. Abortion, when this taint was present, usually took place from the fifth to the seventh month of utero-gestation. Having narrated a number of interesting cases occurring in his own practice, he said that he desired to draw attention to the fact that in these citations the maternal system was thoroughly saturated with the syphilitic virus, and the foetal inoculation was also necessarily complete. Might it not be safely assumed, he asked, that the female is more likely than the male to transmit syphilis to progeny? Again, he went on to say, without claiming too much for the iodide-of-potassium treatment, he could not pass over with justice the query of the late Dr. E. R. Peaslee, whether the success of ultimate maternity may not

be due to the gradual wearing out of the syphilization, as manifested by the occurrence of abortions at necessarily longer intervals, say the third, fourth, and fifth months. He could recall an instance in which a mother, after twelve expulsions of fetuses of various degrees of development, crowned her hopes in her forty-fifth year by giving birth to a healthy boy at full term. In this case chlorate of potassium, in combination with the tincture of chloride of iron, was persistently employed during the last three months of pregnancy.

He then alluded to other maternal dyscrasias acting as factors in causing still-births, such as malarial and uræmic poisoning, the concurrence of eruptive fevers, the implication of vital organs, and the superintention of nervous shocks. Of all these uræmia seemed to be the most prolific of danger, and when this condition existed, as a rule, despite the resources of our art, mother and child were likely to perish together. In scarlet fever in the lying-in chamber, according to his own experience, the child born during the incubation stage of the maternal disease finally escaped contagion altogether. Whether phthisis was essentially a devitalizing agent to the unborn he thought was to be doubted. On the contrary, the generative function expended all its energies in saving the new and jeopardized life.

Passing from the consideration of developmental to that of local causes, with especial reference to fetal deaths occurring before labor, he said it was found that metritis holds a prominent place as a disturber of nutrition. How this was possible could readily be seen, since the uterine mucous membrane was to the placenta what periosteum was to bone, and when metritis was chronic in form the ovum was not likely to retain its vitality any number of months. Malformations of the uterus, although relatively rare, were likewise mentioned as productive agents in the blight of the ovum at any stage of development, but presumably at an early date.

He went on next to discuss disease of the placenta, in regard to which Lusk, in his work on Obstetrics, said: "Many authors dispute its very existence, contending that the morbid changes hitherto referred to placentitis are simply due to retrogressive metamorphosis in extravasations. Other writers affirm its existence, assign to it ætiological relations with metritis and endometritis, and describe its pathology under the following heads: (a) congestion, (b) hepatization and induration, (c) suppuration." Chief among the frequently mentioned causes of still-births was fatty degeneration of the placenta. The term had undoubtedly been abused in the desire to offer the readiest explanation of many phenomena, and had sometimes been adopted to conceal ignorance. The question had been raised in the minds of some, is not the fatty placenta the product of fetal death, and is it not in accordance with the general law in all retrogrades from a higher to a lower organization, as, for instance, in the case of cicatrices, where the reparative method falls away from the standard of the original structure? A certain amount of fatty degeneration was present in any placenta at about the eighth month of utero-gestation, and was, in

some respects, analogous to the process of involution in the uterus itself, or at best, to condense the words of Paget, existed as a defect, rather than as a disease, of nutrition. In this connection, he referred to a paper entitled "Degenerations of the placenta," read before the New York Academy of Medicine by Dr. Charles A. Leah, in which the author adduced some very striking instances that seemed to corroborate the affirmative side of the question. He also read the report of a case to the Cincinnati Academy of Medicine January 19, 1885, by Dr. E. S. McKee, in which a patient who had a number of abortions, due, apparently, to fatty degeneration of the placenta, was treated so successfully with chlorate of potassium, in combination with tincture of the chloride of iron, that she gave birth to living children at full term in two successive pregnancies.

Having referred, in passing, to the alleged condition of tubercles in the placenta, and calcareous, fibrinous, and waxy degenerations, he stated that a certain class of cases were to be regarded as mechanical, both in their origin and effect. To direct blows, falls, and the like, had been attributed many a still-birth, but the number of mothers who had escaped this catastrophe could never be counted. He was inclined to doubt the efficiency of these means in the production of such results, certainly to such an extent as to qualify any direct testimony in a medico-legal examination. Prolapsed funes had contributed their quota toward fetal mortality, this being especially the case when the accident had occurred before the arrival of the physician.

Thus far the matter had been discussed, he continued, from the maternal side; but, as the late Prof. George T. Elliott intimated, there was a side to the question which had never claimed the attention it deserved, and that side could never be fully investigated except in the light of autopsies. The pathology of fetal life was still obscure, and yet he thought its elucidation would probably afford a clue to many a vexed question in this department of medical science. Except when a medico-legal question was raised, autopsies upon still-born children were exceedingly rare, the opposition of the family usually presenting an insuperable barrier to such investigations. Many unexpected conditions were liable to be found in post-mortem examinations of still-born infants, and to a number of these Dr. Shrady now referred. In one reported case no less than two quarts of urine were found in the bladder, and in another there was an umbilical hernia which contained within its sac the liver and almost all the intestines. The condition of the brain explained by far the greater number of cases; intra-cranial effusions of serous character or apoplectic clots of various sizes being found at the autopsy.

The discussion of the paper having been opened by the President, Dr. LEAN, in a few preliminary remarks, in which he called attention to some of the special points treated by Dr. Shrady, among those who participated in it were Drs. Janeway, C. S. Wood, Wm. T. White, Hubbard, Buchanan, Oberndorfer, Hartmann, and Manly.

Dr. JANEWAY referred to a form of degeneration of the placenta that was sometimes met, which had

not been mentioned in the paper, namely, myxomatous. He thought it well to call attention also to another cause of still-births which had not been alluded to, and which he believed to be a very frequent one in New York. This was the use of ergot by incompetent midwives. When one of the Commissioners of the Board of Health he had made a careful investigation of this matter, and had found that the use of ergot constituted a pretty large factor in the etiology of still-births in all cases attended by midwives. Another prominent factor was the fact that in difficult cases of labor the midwives usually waited too long before sending for skilled assistance. These matters he considered important in view of the fact that about one third of all the cases of confinement in New York were attended by midwives.

The discussion was devoted to a large extent to the relations of malarial poisoning to miscarriages, and the question whether it was safe to give quinine to pregnant women. While two or three expressed the opinion that there probably was some danger in the latter practice, and that it was advisable to use quinine, when the drug was indicated, in small doses, but at comparatively frequent intervals, the greater number said they had never seen any injurious effects from quinine, and believed that it could be used with the same freedom in the case of pregnant women as in that of other individuals.

At the conclusion of the discussion the President called attention to chronic obesity as a cause of still-births. Although the pelvic diameters were ample, there might be such obstruction offered by the soft parts of the mother that the child could not be born alive at term, and he related a case in which he had successfully delivered the patient of a living child by resorting to the induction of premature labor.

DR. SHIRADY had also seen cases in which chronic obesity was the cause of the death of the child.

DR. CHARLES A. DOREMUS exhibited

#### A NEW AND SIMPLE APPARATUS FOR DETERMINING THE QUANTITY OF UREA IN THE URINE.

DR. A. FLINT, JR., said that it was always a matter for congratulation when any addition was made to the simple methods at our command of obtaining important results, and he thought that no more important matter could be brought to the attention of the practitioner than such a one for determining the quantity of urea as Professor Doremus had just demonstrated. If looked at from a practical point, excessive accuracy was not called for, and in regard to the few important facts that it was necessary for the practitioner to know about the urine, there were now, with this latest achievement of Dr. Doremus, simple methods in the hands of the profession which could be employed by all with the greatest facility. In connection with the determination of the quantity of urea in the urine he referred to the tests for albumen and sugar.

#### RARE PATHOLOGICAL SPECIMENS.

DR. JANeway then presented two specimens of great interest. The first one, which, he said, illustrated a point in doubt, was from a case of perforating ulcer of the œsophagus, which occurred in a

young child who died of dysentery. The ulcer, which was round, and half an inch diameter, was situated about one inch above the entrance of the œsophagus into the stomach, and not in the posterior, but the left lateral, wall. The point of interest in connection with the case was the fact that the existence of such a peptic ulcer of the œsophagus before death has been denied; and in his recent work on diseases of the throat and nose, including those of the œsophagus, Morell Mackenzie stated that a case of his own which he had reported some time ago as "simple ulcer of the œsophagus," as well as one of Dr. Benson, were too incomplete to be relied on. Mackenzie thought they were open to the objection that the disease may have been of malignant nature, the ulcerated surface not having been submitted to the test of microscopic examination. This, however, he believed was a case of true peptic ulcer, such as was met with in the stomach, and due to the action of the gastric juice upon the mucous membrane. It was a difficult thing to prove just what changes occurred before death, and which were postmortem, in a case of this kind; but the ulcer here in the œsophagus presented precisely the same appearances as those found in the stomach, which were acknowledged by all to give rise to perforation, peritonitis, and death. In the present instance there was inflammation not only of the connective tissue surrounding the œsophagus, but also of the pericardium and left pleura. Again, the odor of the parts was entirely different from the sour odor characteristic of post-mortem gastric digestion. During life, however, so far as could be ascertained, the child presented no signs of pericarditis, pleurisy, or perforating ulcer of the œsophagus.

The other specimen, Dr. Janeway said, was from a case illustrating a rare method of sudden death. It was that of a child who had a mass of enlarged glands on the right side of the trachea, giving rise to tracheal stenosis, and died very suddenly from asphyxia. At the autopsy, a cheesy gland was found at the bifurcation of the trachea, which had produced ulceration, while, occluding the stenosed passage, was a white mass which had become detached from this. In addition, there was a fibroid induration of the upper lobe of the right lung, and a thickening around the bronchi. In connection with the case Dr. Janeway remarked that this bronchial and tracheal stenosis was not uncommon in children.

#### THE DEATH OF DR. E. S. GAILLARD.

On motion of DR. A. FLINT, JR., the following resolution was adopted:—

*Resolved*, That in the death of our late associate, DR. E. S. Gaillard, the profession has lost a bright ornament, medical journalism an able exponent, and a prominent object of our Association—"the maintenance of the honor and character of the medical profession"—an earnest advocate and defender.

—The original lectures delivered by Harvey at the College of Physicians are to be published in autotype from the manuscript in the British Museum, accompanied by a transcript.

CHICAGO GYNÆCOLOGICAL SOCIETY.<sup>1</sup>

REGULAR meeting, February 20, 1885. The President, DR. H. P. MERRIMAN, in the chair.

PROF. CHRISTIAN FENGER, M.D., presented the following report of his anatomical investigation into Prof. W. H. Byford's

"TWO CASES OF MURAL PREGNANCY."<sup>2</sup>

The exact anatomical diagnosis, or minute classification, of an extra-uterine pregnancy is easy enough in the early stages of the disease, but becomes more and more difficult in the latter half and toward the termination of the pregnancy. In the early months it is only by accident that a pathological specimen is found. In the third to sixth month the hæmorrhage from rupture brings some specimens to light, postmortem or by operation, and here the diagnosis is yet comparatively easy. In the latter half, from the sixth to tenth month, the diagnosis, namely, exact location of fecundated ovum, becomes often extremely difficult, next to impossible, on account of secondary changes after partial destruction of Fallopian tubes and ovaries, and still further difficult if a fatal peritonitis has further contributed to mask the normal anatomical features of the organs in question.

The two specimens sent to me for examination belong to the class of late, and consequently difficult, cases, and in one of them decomposition was advanced. Nevertheless, I think that a close examination of the specimens permits of a comparatively exact classification of the two cases in question. Before describing and demonstrating the specimens, permit me to recall to your memories the different forms of extra-uterine pregnancy.

The ovum is arrested somewhere in its normal passage from the Graafian follicle down to the *cavum uteri*, or drops out of the passage, without or after rupture of the latter, into adjoining cavities or spaces.

## (1) Ovarian pregnancy.

The ovum remains in the ovary. Epiovarian pregnancy: the ovum develops upon the ovary, having left the Graafian follicle.

## (2) Abdominal (or peritoneal) pregnancy.

The ovum drops down into the peritoneal cavity, and does not reach the Fallopian tube at all.

## (3) Tubal pregnancy.

## I. Tubo-abdominal, or tubo-ovarian, pregnancy.

## II. Tubal pregnancy (proper).

## III. Tubo-uterine, or interstitial, or mural pregnancy.

## IV. Extra-peritoneal pregnancy (in the broad ligament, after rupture of the Fallopian tube).

(1) Pregnancy on one side of a *uterus bicornis*.

(5) Secondary abdominal or peritoneal pregnancy. Ovary, tube, or even uterus (normal or *bicornis*) is ruptured; the fetus slips into the peritoneal cavity, but remains in connection with the primary sac.

I shall first describe and demonstrate Dr. Byford's case No. 1. The uterus is large, four and a half inches long, three inches broad at the fundus; the

cavity also considerably enlarged. In left side of uterus and vagina I find an incision three and a half inches long, united with silk sutures, leading from the uterus and vagina into the sac, or, as certain members of the Society called it, the adventitious uterus. The sac can only be seen in fragments. Its wall is one to two lines thick, the outside partly covered with peritonæum, partly adherent to surrounding organs, namely, bladder, uterus, omentum. The rectum I do not find. The right ovary and Fallopian tube are missing. The left Fallopian tube shows the following conditions: The uterine portion of the tube is of normal size, passable only for a thin probe, .0005 mm. in diameter; at the distance of half an inch from the fundus it is wider, one eighth of an inch in diameter, and so it continues for four inches; then it suddenly dilates to one inch in diameter, continues so for one inch, and thereafter opens into the fetal sac, the wall of the latter going continuously over into the wall of the tube. The left ovary cannot be found. Large shreds of the sac of the ovum, namely, amnion and chorion, adhere to the sac here and there. The inside of the sac is of dark-brown color, spotted, the color of decomposed blood. This condition is most pronounced in the part of the sac that covers the posterior wall of the bladder and the anterior and posterior wall of the uterus. On the uterus the sac is thinner and more adherent (no subserous connective tissue) than on the bladder, where the wall of the sac is about two mm., firm and movable against the bladder.

From the condition in which we find the left Fallopian tube I think it safe to conclude that the ovum has developed in its outer half, near the abdominal end of the tube. The funnel-shaped dilatation of the tube in this place, and the thickening of its wall, which uninterruptedly continues as the wall of the fetal sac, proves the connection between the two cavities, and this case of extra-uterine pregnancy would thus be of the *tubo-abdominal variety*. I believe that the ovum has commenced its development in the tube, and then, with or without rupture of the latter, has formed its sac on the surface of the pelvic and surrounding abdominal organs. In that respect it might be classified as a secondary abdominal or peritoneal pregnancy, originating in the abdominal end of the tube.

Dr. Byford's case No. 2. This case has a greater interest, partly because the specimen is in a good state of preservation, and partly because some of its features seemingly point to another of the varieties of abdominal pregnancy. In this case, it will be remembered, laparotomy was performed; part of the cyst and the upper two thirds of the uterus were removed. The child I shall not undertake to describe here, as it is irrelevant to the matter in question. We find the uterine appendices of the right side, namely, broad ligament, round ligament, Fallopian tube, and ovary, normal.

The uterus, amputated about the middle of the neck, is of normal size, namely: the cavity one and a quarter inch between the two uterine orifices of the Fallopian tubes; further down, one inch broad; still further down, half an inch broad; and in the neck, a quarter of an inch broad. The average thickness of uterine wall, three fourths to half an inch,

<sup>1</sup> Reported by W. W. Jaggard, M.D.

<sup>2</sup> Chicago Medical Journal and Examiner, January, 1885.

To the left and behind the uterus, and in uninterrupted connection with the surface of the uterus, is the sac, or adventitious uterus. From the anterior surface of the sac, a quarter of an inch from the left corner of fundus, is the left round ligament; it is enlarged a quarter of an inch in diameter. On the upper surface of the sac, behind and to the left of the *fundus uteri*, is a pocket covered with peritoneum, two and one-half inches broad, three to three and one-half inches deep. The upper free border of the pocket, or broad ligament, forms a somewhat thickened ridge, which runs in an arch just to the left, backward, then to the right, then divides into two branches, a lower one that runs around and to the right, and an upper one that runs forward to the left, pointing toward the left corner of the uterus. The ridge contains the left Fallopian tube (the tube is seven inches long, the same as the right tube). It runs to the left backward, in an arch, and then bends to the right downward and backward; here it leaves the broad ligament, and the canal enters the wall of the sac. How it terminates, if on the inside of the posterior wall or not, cannot be surely made out, because the sac is cut off here; but there are no fimbriae, and it does not appear outside of the sac, and has undoubtedly opened into the fetal cavity. The uterine portion of the tube is of normal size, permitting the passage of a very fine probe only; the median portion of the tube is normal, perhaps slightly dilated, three to five lines, six to ten mm. wide. The termination of the tube in the wall of the sac is an oval opening a quarter of an inch in diameter, the borders of which are perfectly smooth; no fimbriae anywhere visible. Of the left ovary no trace can be found. The sac is, on the outside, clad with peritoneum and smooth; the wall of the sac is from one to four to eight mm. thick, white, and firm; the thickest part of the sac is, right behind the fundus of the uterus, a quarter to half an inch thick, and there the tissue, namely, fibres of the uterine tissue of upper surface of fundus, is continuous with the wall of the sac; however, on the posterior surface of neck and fundus, the tissue of uterus is *not* continuous with the sac, but the latter is separated from the uterus by a short layer of connective tissue, which permits of dissection, and leaves the posterior surface of uterus and wall of sac with smooth areas; this is the place where the placenta was situated. The inner surface of the sac has an uneven, ragged, or velvety appearance; most ragged over the placental site, close to and behind the neck of the uterus. Outside of this place there are numerous islands of ragged, uneven appearance, with more smooth parts between them. Several large vessels, a quarter of an inch in diameter, partly free, partly adherent, are found on the inside of the sac.

A microscopical examination of the wall of the sac shows the following:—

(a) In the placental site: (1) an inner layer of free cotyledons or fimbriae; (2) a layer of maternal tissue, with cross-section of the cotyledons; (3) a heavy layer of connective-tissue bundles interspersed with some organic muscle bundles; (4) peritoneum.

(b) A portion of the wall near the peripheral opening of the Fallopian tube into the sac, which

I examined for ovarian tissue, presents exactly the same appearance as (a).

(c) A thick part of the sac, some distance from the placental site, and tube, gives the following:—

(1) An inner layer of areolated connective tissue without cotyledons.

(2) A median heavy layer of connective-tissue bundles, and bundles of organic muscle fibres.

(3) Peritoneum.

(d) A thin portion of the sac presents the same layers as (c).

In considering the anatomical diagnosis of this case, I shall have to take into consideration mural, ovarian, and tubo-abdominal pregnancy.

(1) Can it be a mural or interstitial pregnancy? The continuity of the sac (in the placental site) with the upper surface of the fundus belongs to the signs of mural pregnancy.

The uterine portion of the Fallopian tube is of normal length and width. Consequently the fecundated ovum could not have lodged and developed here. However, a persisting "Gärtner's duct" might perhaps form a lateral branch of the tube, branching off and running in the wall of the uterus. And Baudelocque, the nephew, claims that a mural pregnancy can take place when the fecundated ovum lodges in this blind duct. Kleinwächter in his article, "Tubal pregnancy," in Eulenbergs's Encyclopædia, remarks that this statement of Baudelocque has yet to be proved. But supposing a mural pregnancy had taken place here, and consequently the uterine portion of the tube could be found open outside of the sac, then we lack in this case one essential confirmatory proof, namely:—

The abdominal end of the tube together with the ovary must be found on the outer wall of the sac somewhere, and opening into the peritoneal cavity. Supposing that the ovary, for some reason, was not found and the peripheral end of the tube was obliterated and buried in the wall of the sac, we might yet have had a mural pregnancy. In this case, however, the tube opens into the wall of the sac: if it has opened into the fetal cavity, it cannot be seen on the specimen (however, it looks as if it had done so). The round ligament in mural pregnancy is expected to be pushed outward away from the side of the uterus. This might be different if the ovum could develop in the posterior wall of the uterus; but this possibility has never been proved. Gärtner's duct runs, not in the posterior wall, but from the parovarium, first in the broad ligament (in the same fold as the tube), then in the muscular substance of the lateral border of the uterus and down on the side of the vagina, where it terminates blindly. The sac can be dissected off from the posterior wall of neck and *fundus uteri*, which speaks for the development on the posterior surface of, and not in, the posterior wall of the uterus. Thus, although the positive proof against mural pregnancy, namely, the opening of the tube into the fetal cavity, is wanting (the fault of the specimen), all the signs of mural pregnancy, except the apparent continuity of sac and uterus, are absent, hence I shall declare against mural pregnancy.

(2) The next question then is, is it a tubo-ovarian, tubo-abdominal, or ovarian pregnancy? Of an ovarian pregnancy, we require: (a) that the tube

do not participate in the formation of the sac (Kleinwächter); (b) that ovarian tissue be found in the wall of the sac; (c) that there be a connection between the sac and the uterus through the *ligamentum ovarii*. Nowhere is any trace of ovarian tissue to be found in the walls of the sac.

(3) Of a tubo-ovarian pregnancy, we would require: (a) that the peritoneal end of the tube participate in the formation the sac, that is, opens into the sac; (b) the ovary may be intact, but it may also have been used up in the formation of the sac and have disappeared either entirely or only remnants found in the wall of the sac. (It is easy to see how difficult it might be to find microscopic remnants of ovarian tissue in the wall of a sac one hundred times or more the size of a normal ovary.)

As near as we, in my opinion, are able to come to an exact diagnosis in this case, I should pronounce it a *tubo-ovarian pregnancy*. The exact location of the spot where the fecundated ovum has commenced development, it is, of course, impossible to prove to satisfaction. Still there is one interesting feature in this case, which, in my opinion, throws some light on this point. This is the pocket, the blind pocket, on the upper wall of the sac, behind the uterus. As before stated, the upper ridge of the posterior wall of the pocket, namely, the *ligamentum latum*, or the Fallopian fold of the ligament, forms a circular figure commencing at the left border of the fundus and terminating at about the same point; from the junction of the middle and outer third, a branch goes off downward and to the right. The tube is contained in the first two thirds of the ridge and in the branch. The final third of the ridge, that does not contain the tube, but runs back toward the left corner of the uterus, would, in my opinion, correspond with the *ligamentum ovarii*. The formation of the pocket, clad with the peritoneum and having as upper border the above-described ridge, can, in my opinion, be explained if the ovum has been arrested and commenced development in the ligamentum infundibulo-ovarianum (Hemle) between the fimbriae that line the sulcus leading from the distal end of the ovary to the *ostium abdominale* of the tube. If the ovum is developed here, it can, (1) with the vessels of the chorion, reach the abdominal ostium of the tube, and thus permit the tube to open into the sac; (2) it may reach down on the lower or posterior surface of the ovary and thus during its growth lift up the ovary at the same time as it destroys it, but in lifting it up preserve and enlarge the peritoneal fold or pocket that is normally existing between the posterior surface of the peritoneal fold, containing the tube and the anterior surface of the peritoneal fold, containing the ovary and *ligamentum ovarii*. In case the fecundated ovum, from the ruptured Graafian follicle, had dropped down below the ovary, and had been arrested, or had taken hold on the peritoneal surface of Douglas's fossa or on the posterior surface of ovary; if a development in such a way and place is possible, the pocket could be formed of course, but we could not expect to have the tube run into or open into the wall of the extra-uterine sac. Whether the pocket in question is formed in cases

where the ovum has been arrested in the peripheral end of the tube, I do not know.

On motion, Professor Fenger's report was accepted.

DR. W. W. JAGGARD presented, for Dr. E. C. Dudley, an intra-mural leiomyoma of the uterus. The fundus was more particularly involved; the cavity of the uterus was but slightly enlarged, and the *endometrium* was normal. The tumor weighed about fifteen pounds. Both tubes and ovaries were removed with the uterus. The ovaries had undergone extensive cystic degeneration.

The tumor was removed by abdominal section in the median line with supravaginal amputation of the vaginal portion of the uterus, both ovaries and tubes, on Friday, February 20th, in Mercy Hospital. The pedicle was surrounded by ceraseur and rubber ligatures before amputation; subsequently, the pedicle was secured in Dawson's clamp, and treated after the extra-peritoneal method. The peritoneum was carefully stitched around the lower angle of the incision and the parietal peritoneum was in this manner united to the visceral peritoneum.

DR. HENRY T. BYFORD then read a paper entitled

#### FUNCTIONS OF THE MEMBRANES IN LABOR.

The writer discussed the possibility, probability, and utility of the preservation of the membranes from rupture, until they dilate, or aid in dilating, the vulvo-vaginal orifice, as well as the cervix. [Reserved for publication.]

#### DISCUSSION.

DR. JAMES H. ETHERIDGE thought the paper well-timed.

DR. W. W. JAGGARD, while not prepared to accept the thesis of the paper as a universal proposition, thought the attention to the functions of the membranes, advised by Dr. Byford, would go far to prevent cervical, vaginal, and perineal lacerations, in many cases.

DR. D. T. NELSON said that the membranes, when adherent to the cervix, as pointed out by Dr. DeLaskee Miller, delayed labor. Under these conditions puncture of the membranes was indicated. In practice he tried to find out whether or no the membranes were adherent to the cervix. If adherent, he punctured the membrane; if free, he always waited for spontaneous rupture.

DR. PHILIP ADOLPHUS agreed with the author of the paper in his conclusions, except in case of hydrannion. Under such pathological conditions it was frequently necessary to rupture the membranes in order to secure uterine contractions.

DR. J. SYDNEY KNOX was in the habit of aiding dilatation of the vaginal os with the finger. He was under the impression that the membranes were seldom operative in the dilatation of the vulvo-vaginal orifice.

DR. EDMUND J. DOUGLAS had followed Dr. Byford's suggestion during the past year, and believed the method had prevented perineal lacerations in many cases. Premature detachment of the placenta was a possible danger from delayed rupture of the bag of membranes.

Dr. EDWARD WARREN SAWYER believed that the membranes should not be punctured until the os uteri was dilated to the extent which the pelvis, in the concrete case, would permit. The function of the bag of waters in labor was the dilatation of the os uteri. He ruptured the amnion in one half his cases. There was as great variation in the development of the uterine muscular tissue as in the development of the biceps. Retardation of rupture of the bag of membranes might lead to uterine inertia, or to premature detachment of the placenta. To follow nature's suggestions was a beautiful theory; but nature caused the membranes to be ruptured, in the majority of cases, before dilatation of the vaginal os. He was in the habit of aiding dilatation of the cervix by the introduction of one or two fingers within the canal of the cervix; he also tried to peel off the membranes around the internal os, and was conscious that he had materially influenced, in a favorable direction, the process of parturition. The periphery of the os uteri was less than the periphery of the vaginal orifice. It was inconceivable, under such physical conditions, that the bag of membranes, protruding through a smaller, could dilate a larger, orifice.

Dr. CHARLES WARRINGTON EARLE agreed with Dr. Sawyer that natural processes should be imitated in the puncture of the bag of membranes after complete dilatation of the os uteri.

Dr. H. P. MERRIMAN thought Dr. Byford's paper contained excellent advice for the young practitioner. The thesis could not be accepted as a universal proposition. Dr. Sawyer and Dr. Earle had pointed out the conditions in which the application of the method was contraindicated.

Dr. HENRY T. BYFORD, in conclusion, said that he had distinctly pointed out, in his paper, that the retardation of rupture of the membranes was advisable only in perfectly physiological labors. The members of the Society had called attention to pathological conditions to which the method did not apply.

Dr. Sawyer had read a paper on "Occipito-posterior positions" before the American Gynecological Society during October. A plausible explanation of the fact that anterior rotation did not occur in Dr. Sawyer's thirty-nine cases might be found in the premature rupture of the membranes.

The inaugural thesis of Charles Caldwell A.M. (Dartmouth), M.D. (Harvard), entitled

#### TWO INTERESTING CASES IN OBSTETRICS.

was read by the Secretary.

Adjourned.

### Recent Literature.

*A System of Human Anatomy: including its medical and surgical relations.* By HARRISON ALLEN, M.D. Professor of Physiology in the University of Pennsylvania, etc. Section VI. Organs of Sense, of Digestion, and Genito-Urinary Organs. Philadelphia: Henry C. Lea's Son & Co., 1885.

The volume before us completes Dr. Allen's Anatomy. It contains, in addition to the description of the parts named above, chapters on super-

ficial and topographical anatomy, on embryology and on the methods of making post-mortem examinations. We are struck, as we were in our study of the earlier volumes, by the vast labor the author has given to the work. This is shown by the condensations of the writings of a multitude of investigators and by references to scattered and not easily accessible papers on both anatomical and clinical questions. There is much to praise in the way this knowledge is presented.

Professor Allen appears to take particular pleasure in the parts that treat of the pharynx, the month, the teeth, and the soft palate. The remarks on the tongue are good and interesting, but we miss a description of the interlacing muscles that compose it. The remarks on the liver that follow the account of its structure contain much from Ludwig Mayer's work on the wounds of the liver and gall-bladder. He reproduces five figures of frozen sections that show the liver with its relations. We must remark, however, that figure 180 representing a sagittal section in the mammary line certainly does not show the normal liver of an adult. Mayer's tables showing what viscera are wounded by projectiles passing between certain points on the surface are very instructive, though these points are not always defined as accurately as could be wished. This remark applies even more forcibly to the section on penetrating wounds from the same work. What do we learn by being told that a knife-wound of the right side of the abdomen three inches long and three quarters of an inch wide wounded the liver? We would mention Professor Allen's remarks on the effect of the movements of the viscera on the bile-duct as a happy instance of applied anatomy.

We notice a very annoying mistake concerning the action of the crico-thyroid muscle. We are told that it has a fixed point in the cricoid cartilage and draws the thyroid down, and a foot-note explains that formerly the opposite opinion prevailed and that the views given in the text are based on the researches of Dr. F. H. Hooper. The fact is that Dr. Hooper showed that the thyroid is the fixed point, which was contrary to the then generally received theory. It is evident that this error is the result of an oversight. We have now and then to regret a want of accuracy. It is not stated whether the main fissure of the lung ends in the anterior or the inferior surface. The vexed question of the origin of the bile capillaries and their relation to the liver cells is practically ignored. We are surprised that in a work of this scope so little is said of the skin. Nothing is said of the direction of the hairs, nor of the direction in which the skin retracts when cut in different regions. There is a slight allusion to the ridges formed by papillae, but none to Dr. Warren's fat columns.

The chapter on Superficial and Topographical Anatomy does not treat of the positions of most of the internal organs, as this matter has been discussed in the course of the work. The author takes occasion to defend in a foot-note the statement made in an earlier volume that in lumbar colotomy the quadratus lumborum may be divided with advantage and quotes Dr. L. McLane Tiffany in support of his view, which is undoubtedly correct.

## PROTECTION OF THE PURITY OF WATER-SUPPLIES.

The latest reports — reports which if not true are in all probability only premature — indicate that cholera has broken out in Southern Russia and reappeared in Toulon. Of the importance of guarding water-supplies from sewage or other contaminations at all times, but especially at the present moment, there can be no question. Unfortunately, the difficulty in thickly settled regions of preserving the purity of these supplies is even more generally realized. No problem in the near future in our older States will demand more wisdom on the part of Legislatures or more discretion and good sense on the part of constituency than this one of protecting water-supplies.

An important decision has just been rendered by Mr. Justice Allen, of the Massachusetts Supreme Court, in the case of *Martin vs. Gleason*, or in other words, the *City of Boston vs. the Town of Natick*, which illustrates the difficulties of these problems, and the sort of dangers to which modern water-supplies expose large centres of population. As in Massachusetts, so in all our thickly settled States it will be found that, in this matter, the interest and convenience of the large cities and the country towns, of the dense centres of population and the scattered hamlets, farmhouses, and factories, are antagonistic. This antagonism makes itself felt in the Legislatures to the disadvantage of the large cities.

The town of Natick, a place of about 10,000 inhabitants, many of whom are devoted to shoemaking, has been in the habit, for years, of emptying the refuse of its water-closets and shoe-shops into Pegan Brook, a small stream, which presently, after a course of less than half a mile, empties into Lake Cochituate or Long Pond, from whence the city of Boston takes, and has taken for many years, a considerable portion of its water-supply. The medical fraternity have felt that, apart from the aesthetic view of the question, the inhabitants of Boston sup-

We must disagree with him, however, when he states that the fold of the buttock corresponds with the border of the *gluteus maximus* in tonic contraction. It has been shown that in the cadaver the border of the muscles forms a considerable angle with the fold and we cannot conceive that any amount of contraction should make them coincide.

There is much of interest in the chapter on embryology and malformations. Here again the subject is not treated as a whole, for a good deal has already been said on the development of organs, and it appears to be the author's purpose to give a general view of the plan of development which should serve as an introduction to the study of malformations. He quotes at considerable length from Foster and Balfour.

The index at the end of the book is twofold. There is first a general index and then a clinical one.

It remains for us to sum up our criticism on the work as a whole. It is good; it deserves perhaps even stronger praise, but yet we cannot deny a feeling of disappointment. Professor Allen's plan was a great, indeed a gigantic one. It involved nothing less than a complete treatise on anatomy presenting at once its scientific and clinical aspects; a work that should be at once a textbook for the student and to some extent an encyclopedia for the practitioner. To achieve perfect success in such an undertaking would imply writing one of the most remarkable works on anatomy that the world has ever seen. To fall even considerably short of this is not discredit. We do not believe that this book will take the place of the well-known textbooks now in use, which have reached their present degree of perfection by the gradual improvement of successive editions; but it will find its place in the library, not only of the teacher of anatomy, but in that of the well-read practitioner.

T. D.

## MORE TELEPATHY.

*Mr. Editor.* — As another contribution to the long array of cases illustrative of this phenomenon, I wish to add one from my own experience.

In 1879 I was a passenger on the late notorious steamer *Queen*, and bound for Liverpool. In my stateroom was a lounge or sofa, with a rattan seat, which was placed under the ports. I was lying on this sofa one afternoon just before dinner, thinking of nothing in particular, when I heard distinctly the voice of one of my young children, at home in Philadelphia, calling "Papa! Papa! help me!" The occurrence startled and distressed me, and as it was impossible for me to hear from my family for at least a week, I had an anxious voyage, although gradually the circumstance ceased to affect me so strongly.

I was reassured ultimately by a letter from my wife, written subsequent to the occurrence, in which no mention was made of any calamity, and on my arrival home and comparing the hour, with due allowance for difference of longitude, I found that at the precise time my children were at their dinner and the call I heard "Papa! help me!" was but another instance of that want of good manners in children, which we all deplore but find it so difficult to correct.

Yours respectfully,

A. CARVER.

plied with Cochituate or Long Pond water were at the mercy of any case of typhoid fever in Natick which might empty its faecal evacuations into Pegan Brook, and with possibilities of cholera the uneasiness would have been greatly increased.

Under the law of 1878, Section 96, Chapter 80, of the Public Statutes:—

"No sewage, drainage, or refuse or polluting matter, of such kind and amount as either by itself or in connection with other matter will corrupt or impair the quality of the water of any pond or stream, hereinafter referred to, for domestic use, or render it injurious to health, and no human excrement, shall be discharged into any pond used as a source of water-supply by a city or town, or upon whose banks any filter basin so used is situated, or into any stream so used, or upon whose banks such filter basin is situated, within twenty miles above the point where such supply is taken, or into any feeders of such pond or stream within such twenty miles."

The State Board of Health was given general supervision of all streams and ponds used by a city or town as sources of water-supply, with reference to their purity, and upon application of a city or town to the State Board, alleging the pollution of its water-supply, by the violation of any of these provisions, the Board was to give notice and grant a hearing, and upon proof of the violation issue orders enjoining the continuance of the nuisance. A right of appeal, however, from such an injunction to a sheriff's jury was reserved. As such a jury was necessarily taken from the neighboring inhabitants, the injunction issued by the Board was invariably dissolved and the act rendered practically inoperative as far as the grievances of the large cities were concerned.

As Boston found the existing law inadequate to protect her, additional legislation was sought, and, in the meantime, measures were taken to dam off and filter the waters of Pegan Brook. The same sort of difficulties were encountered in obtaining new legislation as in enforcing the provisions of the old statute. The lawmakers from country towns are, of course, largely in the ascendant in any Legislature, and good care was taken that they should be given their full proportion of representation upon the committee for water-supply and drainage. It was, therefore, difficult to get before the Legislature.

Under these circumstances the legal adviser of the city bethought himself of the ingenious device of applying to the Committee on Public Health, for the regulation of water as a "beverage." The committee entertained the application, but finally, in consideration of much opposition and dissatisfaction on the part of the Committee on Water-supply and many members of the Legislature, the question was referred to the Committee on the Judi-

ciary, which a year ago reported an amendment, subsequently passed, to the following effect:—

"The supreme judicial or superior court, in term time or vacation, upon the application of the mayor of a city, or the selectmen of a town interested, may grant an injunction against any violation of the provisions of section ninety-six of chapter eighty of the Public Statutes."

At the same time, the question was removed from the jurisdiction of the Board of Health and of sheriff's juries.

Under this amendment suit was brought by the city of Boston against one Gleason, an inn-keeper, emptying his refuse into the brook. An injunction was obtained and was granted by the court in the decision of Mr. Justice Allen above referred to. Whether this decision will convince the inhabitants of Natick that they will not be allowed to pollute the water-supply of Boston, or whether further injunctions and possibly further legislation will be required, remains to be seen. At least a considerable, and at the present moment especially gratifying, step has been taken in advance toward the protection of water-supplies.

The difficulties and delays encountered in reaching the present position in Massachusetts are liable, as we have said, to occur elsewhere, where the interests of country districts and large cities clash—as they sooner or later must—and the history of this struggle between Boston and Natick may offer some useful hints in the future.

#### CURARE—JUCUNDE.

WHEN the great Asclepiades gave his classical definition of the object of medical treatment he was too wise not to insert the adverb *jucunde*. Nor, we may believe, was it added merely as an afterthought. Indeed, it is not unlikely that it was intended to form a climax with the *eido* and the *tute*. If his disciples have sometimes erred in not giving due weight to the æsthetic element in their prescriptions there is evidence that they are beginning to awake to its importance. When we have seen a great popular medical delusion grow and thrive on the mere foundation that sugar is sweet and water has no taste, we recognize the potency of the palate, and think we see a new force in the words of the apostle who compared the *lingue* to the small helm by which the great ships are turned about "whithersoever the governor listeth."

Nor is it to be wondered at that persons of delicate sensibilities, especially under the depressing influence of sickness, should be acutely susceptible to the influence of the palate. With such persons it becomes a matter of more than æsthetics, of actual therapeutics, to administer all the *mgesta*, medicinal as well as dietetic, in an acceptable form.

There are happy exceptions to the general standards of taste. We have all seen patients who enjoy a clean, sharp bitter. An occasional child, brought up on the *oleum morrhue* as upon his mother's milk, takes it with gusto, and even rolls it as a sweet morsel under his tongue. But, unfortunately, nature has invested many of her most useful medicaments, which, from the very fact that they have capacities for good, have also corresponding capabilities of harm, with a taste sufficiently pronounced and disagreeable to put men on their guard against recklessly partaking of them. It has been suggested that, as the pain sense is to give warning of physical injury, so nausousness is a danger-signal of poisons and active drugs. This may be, and yet there are certainly some exceptions. Arsenic is tasteless, and so is calomel. (Was the old-time abuse of this drug, by the way, due to its lack of taste?) Doubtless much can be done to render palatable most of the remedies in common use by suitable vehicles and methods of combination.

A recent correspondent of the *Therapeutic Gazette* gives expression to what we think is beginning to be widely felt, namely, the importance of making prescriptions palatable. He demands with considerable force more definite instructions from our therapeutic teachers on this point. The accomplished editor of the journal referred to has something to say upon the subject, enough to show the scope and possible value of a more extended treatise in this field, which we should hail with pleasure. For instance, he points out that the citrate of potassium can be largely masked by the free use of lemon juice. Muriate of ammonia is largely covered by licorice, provided the latter be added in such quantity that there will be ten to fifteen grains of it for every ten grains of the muriate. The addition of glycerin to a mixture containing an ammoniacal or other irritant salt often has the most happy effect in obviating the acidity. It must not be forgotten, however, that glycerin throws out of solution most alkaloidal salts. This is essentially important in connection with the fact that the addition of glycerin to the tincture of the chloride of iron is most advantageous from the aesthetic point of view. We are very apt to combine tincture of chloride of iron with salts of quinine, strychnine, or other alkaloids. Even when such solution is very strongly acid, glycerin precipitates the organic principle. Syrup of squills, syrup of ipecac, and most other sweet expectorants, can readily be masked by the syrup of wild-cherry bark, provided cyanide of potassium (at least one twentieth of a grain to a dose) be added to intensify the prussic-acid taste. The excessive sweetness of these mixtures is disagreeable to some individuals; this, of course, can readily be obviated by the addition of lemon juice or other acid.

It is also pointed out that it seems to be a tradition of the profession that cough remedies should

be administered in mixtures, while there is no reason why they should not be given in pill form. Expectorants as well as cathartics could be given in pills, and there seems no reason why copala should not be enclosed in capsules when prescribed for chronic bronchitis, as when given for gonorrhoea.

A practice often complained of, and with considerable reason, by our most competent dispensing pharmacists, namely, the specification in physicians' prescriptions of the preparations of some particular manufacturing chemists, rests largely upon the fact of the greater palatableness of such preparations. Druggists say with justice that they can make equally agreeable combinations if the prescriber will only give his directions, or even if left to themselves. But permissive prescriptions, allowing the dispenser to select his own vehicle and method of combination, and prescribing only the active remedy or remedies desired and the strength per cc., while they might under occasional circumstances be allowable, have yet certain great and obvious objections in the too great responsibility placed upon the dispensing clerk and the possibility of his introducing as a mere vehicle what has a medicinal influence. So that it is as a rule desirable that the physician should either direct or know the entire composition of every medicine his patient takes. Palatable magistral prescriptions to be filled by the dispensing apothecary require just such knowledge on the part of the physician as the correspondent above referred to asks for. A work on this subject would come most naturally from an accomplished pharmacist, and while it should contain correct examples sufficient to make clear the principles laid down, should be much more than a mere medical receipt-book. Of the latter we have already more than enough. Pharmacodynamics is doubtless the highest branch of therapeutic science, but for those who practise the art of medicine it is as important to answer the question how, as what or why.

#### THE CARNEY HOSPITAL.

In the year 1863 the late Andrew Carney, of Boston, purchased, at a cost of \$13,500, the piece of ground where the Carney Hospital now stands, and presented it to the community of Sisters of Charity, that it might be used for its present purpose. It stands upon one side near the summit of the famous Dorchester Heights, from whence Washington forced the evacuation of Boston by the British troops. The superb view on all sides and the pure air and sunshine which reach it from all quarters indicate the spot, though in close proximity to a poor and thickly settled portion of a great city, as admirably adapted to the purposes to which it has been devoted. The present brick building was erected in 1865 at a cost of \$108,000, Mr.

Carney having added \$56,700 to his original gift, and represents only one wing of the proposed structure. Additional land was purchased some years ago by the Sisters to secure an unbroken frontage on three streets, a purchase which increased the debt which they were compelled to assume upon the building itself.

They have carried on their hospital all these years with constantly increasing success and usefulness in the absence of any endowment through periods of prosperity and adversity, under temporary discouragements which would have disheartened less zeal than theirs, and this year, in their annual report, make the gratifying announcement that the hospital is at length entirely free of debt. This consummation, however, seems to be only an incitement to fresh exertions, and the Sisters now appeal to the community to aid them to realize the original plan of the building by completing the other wing.

In addition to the usual medical and surgical wards and out-patient departments, the Carney Hospital, in its private rooms, offers unusual facilities not to be found elsewhere. Any patient occupying a private room can be treated by the physician of his choice, whether a member of the Hospital staff or not, provided he be a regular practitioner of medicine. Such a provision is often of great convenience both to doctors and to the sick.

The situation of the building has proved especially favorable to the success of surgical operations, and, through the generosity of Dr. C. G. Weld, formerly connected with the hospital, it is now provided with a complete set of surgical instruments of the most recent and approved pattern.

One other feature of the Carney Hospital which should commend it to the public is that it receives and cares for chronic cases, a class for which the provision in every community is always too limited. Although the majority of the patients in the wards are Roman Catholics, no discrimination is made on account of race, color, or religion: in this sense the Sisters proclaim themselves as truly Catholic.

#### MEDICAL NOTES.

— Dr. Lucas Champonnière recommends (*Journal de Médecine*, 1881), in the treatment of epistaxis, the introduction into the nasal fossa of a bit of finely cut sponge saturated in vinegar or lemon juice. The patient is then made to lie on the abdomen and the blood, instead of trickling back into the pharynx, flows upon the sponge and forms a clot.

— Dr. W. S. Playfair, in a recent lecture on Emmet's operation of Trachelorrhaphy, says, with regret, that he thinks his countrymen have not given the operation sufficient consideration, but, prejudiced by the too great enthusiasm with which Americans

have regarded it, have resorted to the opposite extreme of distrust. Dr. Playfair thus sums up his own views upon it: "In bringing this subject before you my object has been to direct your attention to a means of cure not to be often resorted to, not a panacea, but an occasional resource in obstinate cases of the utmost value, which has been strangely underestimated amongst us. I am no fanatical supporter of the operation, and am quite sure that it is only in a fractional proportion of cases of even marked laceration that it should be performed. It is not because a cervix is lacerated, even badly, that it should be done, but only because such lacerations are accompanied by serious troubles, in which other means of cure have been persistently tried in vain."

— Cocaine has been used with good effect by M. Bouché in difficult dentition. It is mixed with a suitable vehicle and rubbed on the painful gums four times a day.

#### NEW YORK.

— On the steamer City of Para, of the Pacific Mail, which arrived at quarantine March 24th, two fatal cases of yellow fever occurred: one among the cabin passengers and one among the steerage, during her voyage to New York. On the nineteenth of March, three days after leaving Aspinwall, both patients died and were buried at sea. As there had been no sickness on board after that date, the vessel was allowed to come up to her dock in the city on the 25th, after having been detained at quarantine for a day and having been thoroughly fumigated.

— The certificate of incorporation of the Sanitary Aid Society of the Tenth Ward was filed in the county clerk's office March 21st. Its objects are "to improve the sanitary condition of the tenement-houses and the comfort of the tenement-house population of the city of New York, beginning with the tenth ward, by a system of inspections and reports, for the purpose of encouraging a stricter observance of sanitary regulations, and by such other similar and concomitant means as may be legal and conducive to such business and objects." The tenth ward is selected to begin in, as being the most crowded with tenements and in the worst sanitary condition. The Board of Health has ordered a thorough house-to-house inspection of the entire city, and, in order that the work may be done more systematically and satisfactorily, the city has been divided into fifteen districts. The inspectors having charge of it, who are selected from gentlemen already connected with the Health Department, and the boundaries of the districts, have just been announced in a circular issued by Dr. Moreau Morris, chief of the First Sanitary Division.

The Ladies' Health Protective Association held a mass meeting at Steinway Hall on Saturday evening, March 28th, at which Judge Noah Davis pre-

sided, and addresses were made by General Alexander S. Webb, president of the Tenth Ward Sanitary Aid Society; Dr. John C. Peters, sanitary engineer; Charles T. Wingate, and others.

—A petition signed by a large number of the wholesale butter merchants has been sent to Albany in support of a bill amending and making more effective the act of last April, to suppress the manufacture of oleomargarine, as it has been found not sufficiently stringent.

—Thomas Cabot, aged one hundred and three years, died at the Home for the Aged, in Brooklyn, March 25th. He was born in Dublin, and came to this country fifty-three years ago.

## Miscellany.

### THE BEES AND APOLLO.

A MEDICO-PHARMACEUTICAL FABLE.

ONCE upon a time the Busy Bees were gathering honey from a flowery field on famed Hymettus. Suddenly, one Bee was heard to buzz much more loudly than the rest of his companions, who, upon listening, heard that he had found a new process for extracting a superior Honey of remarkable medical properties. He had also at the same time invented a very ingenious way by which he could with Comparative Ease make his Buzz sound four times as loud as that of the ordinary-Bee. By means of these inventions he soon disposed of large quantities of Honey at a High Price. But one day Apollo, who was experienced in the matter of Honey and its medical properties, came that way seeking some good sample for the use of his friend Diana who was a little ill. He looked at the new preparation which was put up in soft capsules and called Honeyine, and at another kind which was put up in chocolate tablets and called Honeyidea. He also listened to the new Buzz. "I think," he said, finally, "that the Buzz is much more wonderful and effective than the Honey; I will take it to Diana, who is fond of buzzing."

Some days later, Æsop, on hearing this story, remarked that the Moral which he would add was that the Art of Advertising a new medicinal preparation is of more importance than the Art of making it.

M. S.

### EPIGRAM

On a gravestone in a country churchyard in England, on Mrs. Arabella Greenwood, who died in childhood; written by the Rev. Mr. Greenwood. D.D.:—

O Death! O Death! thou hast cutt down  
The fairest Girl, & soon in all this town;  
Her virtues and good qualities are such,  
That shee might have married a lord or a judge,  
But such was her condescension, and such her humility,  
She chose to take me, a Doctor of Divinity,  
For which herolcke arte, she stands confesse  
Above all others the Phoenix of her sexe,  
And like that birdce one younge shee did begette,  
That she might not leave her sexe discomolate.  
Me grieft for her is so verie sore  
I can onlie write two lines more:  
For this, and everie good woman her sake,  
Never let a bilsterre be putte on a lyfge in woman's backe.

—Boston Weekly Magazine, December 17, 1803.

### AUTO-CÆSAREAN SECTION.

The British Medical Journal (February 21st) publishes an astonishing and wellnigh incredible case, which, however, was vouched for by Dr. von Guggenberg, who, in fact, exhibited the patient at the last annual meeting of Bohemian physicians at Tetschen.

On September 28, 1876, he was summoned at two in the morning to see a woman, who was said to have cut open her abdomen. He found the patient lying in a miserable house, on a wretched and dirty bed, exhausted and bloodless, and only capable of making affirmative and negative signs. On removing a dirty petticoat which covered her, an incised wound was seen on the right side of the abdomen, passing downward and inward, from which a somewhat large coil of intestine protruded, the greater part of which, covered with dried blood, rested upon a dirty blood-soaked straw sack. Hemorrhage seemed to have ceased from every part of the wound, and the uterus was contracted to the size of a child's head. A fully developed, but dead, male child lay between the patient's knees.

Clean linen was procured from a neighboring house, and, with a piece soaked in oil, the protruded intestines were carefully wiped and returned, and the wound sewed up, the peritoneum being included with the skin. The incision was about three and one-half inches long, and slightly S-shaped. It was dressed with a five per cent. carbolic solution, fixed with strapping, and the abdomen was carefully bandaged. By the afternoon the patient was able to speak, and next day the history was taken. She had had seven children previously, four of whom had been born without medical assistance, two with forceps, and one after craniotomy. The pains began between September 24th and 25th, ceased in the afternoon, and came on again on September 26th, when the midwife stated that she felt the presenting head on vaginal examination. On September 27th, convulsions came on, according to the patient's account, accompanied by agonizing pain and great distension of the abdomen, the movements of the child ceasing. The pain and distension became so severe that the patient determined to perform Cæsarean section, of which she had heard. She, therefore, took a razor, and divided the skin slowly; she then made a second and third incision; and finding the child not yet appearing, made another cut, which caused a large jet of blood to escape, and exposed the placenta; this she removed.

One foot of the child came into view, which she seized and pulled upon until the whole of the body came through the wound, the head requiring the exertion of all her force. She divided the umbilical cord, laid the child (which she believed to be dead) beside her on the bed, and threw the placenta on the floor. She had passed neither urine nor feces since September 24th. The progress of the case was very good; urine was passed on the afternoon of September 28th, but the first stool not till October 2d. The pulse reached 120 on the day after the operation, but was never again so frequent; the temperature is stated to have not been very

high; and, although there was a considerable amount of exudation from the wound, it had united by October 3d. The patient soon returned to work, and has been ever since in perfect health.

## Correspondence.

### ROLLER-SKATING.

DAYTON, OHIO, March, 1885.

*Mr. Editor.*—I noticed in your issue of March 5th, a communication headed "Roller-Skating.—An opportunity for collective investigation," etc., signed "Questioner." I desire to call the attention of the profession in general, as well as that of Questioner, through your valuable columns, to a recent experience I have had with the so-called "exercise" of roller-skating. Mrs. L. consulted me about two of her little girls, Anna, aged ten, and Eva, aged twelve years. The mother called my attention to a leucorrhœal discharge which she lately observed on their clothing. An examination of the parts verified the mother's statement. I told her I could not account for it, as I had already seen it in children younger than hers, but the lady, who is of rather extraordinary intelligence, advanced a theory that their recent excessive indulgence in roller-skating brought on their affliction. Certainly, I partly coincided with her sentiment. When she returned home and spoke to other ladies about the matter it brought out the fact that there were many others afflicted the same way. In fact, I examined nine children in forty-eight hours, whom I found affected with leucorrhœa. These children were all roller-skaters, from nine to sixteen years of age. Their mothers steadfastly maintained that they were not afflicted before they commenced the so-called exercise. I have reason to believe that the practice of roller-skating exercise is injurious to young females by reason of the excessive movements of the lower extremities, especially of the pelvic organs, including the walls of the vagina. I trust the profession everywhere will record cases of this nature that may come under their observation, which will, I am sure, reveal many valuable pathological changes, caused by the exercise of roller-skating.

Very truly yours,

CARL H. VON KLEIN.

### THE LECTURE SYSTEM.

HANSON, MASS., February, 1885.

*Mr. Editor.*—From time immemorial it has been the custom, in medical schools, to teach by means of lectures. Is this the best method? I think, and shall try to prove, that it is not.

A man, in order to graduate, must buy tickets for two courses of lectures, but is this proof of study or knowledge? No, far from it; it is not even proof that the student has attended the lectures. It is not an uncommon thing for a man to buy the tickets and then neglect to attend a part, or even the whole, of the course. And if the student attend every lecture, is that to be accepted as proof of any knowledge of the subject? No; many devote the lecture hour to whitening a stick, or the seat, carrying on a whispering chat with a chum, or taking a nap; and the student who apparently is a most attentive listener, perhaps is thinking about the good time he had last night, or is to have to-night. If the teacher is a rapid lecturer, the student has not time to give a point a second thought in order to thoroughly understand it or to

commit it to memory; and if he tries to take notes, he can get but a word or two here and there.

In some schools the lecturer speaks very slowly, just as fast as a man can conveniently write and the students take every word. Here the student is so engrossed with the mechanical effort of copying every word that the lecture has done him little good. At the end of the course, the student has produced a few poor textbooks, when he might have bought good ones for a few dollars, and much of his time and money has been thrown away. Of course the slow lecturer does not get over much ground in an hour.

All needed medical knowledge can be found in our textbooks.

If this *must* be read aloud, why can it not as well be read by one of the students or even by one who has no knowledge of medicine? Why is it necessary to employ a man at a salary of one or two thousand dollars? Some will say, this man has had experience. So has the writer of the textbook.

The objections to a reliance upon lectures, for instruction, are many.

What the student does not at once understand, he must pass over; he does not have time to reflect upon a thought, and then commit it to memory. When the lecturer makes a statement, if the student does not catch it, and in an instant understand and remember it, it is lost to him. What he reads in a book, he can read over and over again until he understands it, and can remember it, and even if he forgets it he knows where to find out all about it, and our education is rather to teach us where to find things, than to remember everything.

Medical instruction should be given by means of textbooks, instructors or teachers, daily recitations of stated lessons, and laboratory work. Each teacher should not have any more students in his class than he can hear recite in an hour. He should have a pack of cards containing the names of the students, one name on each card. He should shuffle the cards, deal off the top one, and call the name for that student to recite. In this way he finds if any are absent; he cannot give a favorite the easy part of the lesson. The student does not know what part he will be called to recite, so must learn the whole. He does not know *when* he will be called, so must keep his mind on the recitation all the time. The student should be allowed to ask any relevant question, and the teacher should devote a third or one half of the hour to explaining, showing specimens, illustrating by blackboard diagrams, etc.

Now, when daily recitations are not enforced the students hang around the college building, attending such lectures as especially interest them, until about time for the examinations; then they look over the old examination papers and find out about what kind of questions are asked, and just how much they must know in order to squeeze through; then they cram day and night until the examination. Many know nothing of the minutiae.

Recitations are much better than lectures, but laboratory and clinical work is much better than recitations. Anatomy (normal and pathological), chemistry, physiology, and materia medica should be taught almost entirely in the laboratory. The student should study the *thing* rather than the book; yet the book should be studied enough so that the student will be familiar with every part of it, as he will not always have the specimens to refer to. Surgery, theory and practice, and obstetrics should be studied, mainly, in the operating-room and at the bed-side. The recitations should be upon the textbook, laboratory, and clinical work.

Although I object to the schools obliging the students to pay men large salaries to read them lectures which they could read much better in their own rooms, the teacher who hears the recitation should be a man learned in his own department, that he may explain

any point which may arise and not be caught napping by a brilliant student, and the students could afford to pay such a man a good salary. Every student should be required to attend every recitation and not be excused from any clinical or laboratory work. Many will refer to German schools to show the benefit of the lecture system. All will admit that a large part of the German students are negligent and idle. The judgment of many of the most intelligent professors and

educators in Germany is in favor of modifying the lecture system by introducing instructions by recitation to a large extent. Nothing is more unsatisfactory in the judgment of one who sees beneath the surface, than the superficial habits and narrow culture of the students in those schools in which the instruction is given chiefly by lectures.

Very truly yours,  
FLAVEL S. THOMAS, M.D. (Harv.).

REPORTED MORTALITY FOR THE WEEK ENDING MARCH 21, 1885.

Deaths reported 2,876; under five years of age 969; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrheal diseases) 361, consumption 42, lung diseases 532, diphtheria and croup, 137, scarlet fever 59, measles 49, typhoid fever 33, diarrheal diseases 25, whooping-cough 20, cerebro-spinal meningitis 18, malarial fevers 14, puerperal fever 13, erysipelas 12. From typhoid fever, Philadelphia 12, New York, Brooklyn, and Baltimore three each, St. Louis, District of Columbia, New Haven, Nashville, Worcester, Fall River, Lawrence, and Haverhill one each. From diarrheal diseases, New York seven, Brooklyn five, Fall River three, St. Louis, Lawrence, and Chelsea two each, Boston, District of Columbia, Milwaukee, and New Haven one each. From whooping-cough, New York 11, Philadelphia four, District of Columbia two, Boston, St. Louis, and Providence one each. From malarial fevers, New York nine, Brooklyn two, Philadelphia, New Haven, and Fall River one each. From cerebro-spinal meningitis, New York and Philadelphia four each, Fall River three, Holyoke two, St. Louis, Cincinnati, Lowell, Springfield, and Haverhill one each. From erysipelas, New York five, Philadelphia, Brooklyn, and Boston two each, District of Columbia one.

One case of small-pox was reported in St. Louis; scarlet fever 46, measles 36, diphtheria 22, and typhoid fever four.

In 123 cities and towns of Massachusetts, with an estimated population of 1,417,895 (estimated population of the State 1,355,101), the total death-rate for the week was 19.30 against 19.18 and 17.75 for the two preceding weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,906,146, for the week ending March 7th the death-rate was 20.6. Deaths reported 3,515; infants under one year of age 851; acute diseases of the respiratory organs (London 371, measles 133, whooping-cough 112, scarlet fever 42, fever 33, diarrheal 28, diphtheria 21, small-pox (London 16, Liverpool and Manchester two each, Birmingham, Birkhead, and Sunderland one each) 25. The death-rates ranged from 11.8 in Brighton to 37.6 in Cardiff; Birmingham 17.7; Blackburn 19.9; Bradford 21.7; Leeds 19.1; Leicester 22.2; Liverpool 22.5; London 19.1; Manchester 26.9; Nottingham 21.4; Sheffield 17.6; Sunderland 15.2. In Edinburgh 18.5; Glasgow 29.1; Dublin 32.7.

For the week ending March 7th in the Swiss cities there were 37 deaths from consumption, lung diseases 32, diarrheal diseases 18, diphtheria and croup eight, small-pox, measles, and puerperal fever three each, erysipelas and typhoid fever two each, scarlet fever, and whooping-cough one each. The death-rates were: at Geneva 19.2; Zurich 17.5; Basle 23.1; Berne 30.6.

The meteorological record for the week ending March 21st, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Date.	Barom-eter.	Thermometer.				Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.
		Daily Mean.	Daily Mean.	Maximum.	Minimum.	7.23 A. M.	3.23 P. M.	11.23 P. M.	Daily Mean.	7.23 A. M.	3.23 P. M.	11.23 P. M.	7.23 A. M.	3.23 P. M.	11.23 P. M.	Duration, Hrs. & Min.	Amount, in Inches.

# OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MARCH 21, 1885, TO MARCH 27, 1885.

HAVARD, VALÉRY, captain and assistant surgeon. Leave of absence extended one month. S. O. 65, A. G. O., March 21, 1885.

RAYMOND, H. I., first lieutenant and assistant surgeon. Assigned to duty at Fort Gaston, Cal., post surgeon. S. O. 30, Department of California, March 20, 1885.

# OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE WEEK ENDED MARCH 21, 1885.

SAWTELLE, H. W., surgeon. Detailed as chairman of Board for physical examination of officer of the Revenue Marine Service. March 17, 1885.

ARMSTRONG, S. T., passed assistant surgeon. Granted leave of absence for thirty days. March 16, 1885.

AMES, R. P. M., passed assistant surgeon. Detailed as recorder of Board for physical examination of officer of the Revenue Marine Service. March 17, 1885.

## SOCIETY NOTICE.

SUFFOLK DISTRICT MEDICAL SOCIETY.—The *Section for Clinical Medicine, Pathology, and Hygiene* will meet at 19 Boylston Place, on Wednesday, April 23d, at 7.45 o'clock. The following papers will be presented: Dr. F. E. Doggett, "Metallic Poisoning from Canned Foods, with a Report of Six Cases of Poisoning from Canned Tomatoes." Prof. E. S. Wood, Ass't. Prof. Wm. B. Hills, Dr. Charles Harrington, Dr. S. W. Abbott, Dr. S. H. Durgin, and Dr. C. E. Folsom are expected to take part in the discussion. Dr. T. A. de Bois, "Two Cases of Retro-pharyngeal Abscesses." Drs. F. L. Knight, S. W. Langmaid, and F. H. Hooper will open the discussion.

ALBERT N. BLOMCHART, Secretary.

## BOOKS AND PAMPHLETS RECEIVED.

Remarks on Typhoid Fever in the Young. By A. Jacobi, M.D., etc., etc. (Reprint.)

Seventy-first Annual Report of the Trustees of the Massachusetts General Hospital and McLean Asylum. 1884.

The Physician Himself and what he should add to his Scientific Acquirements in order to secure Success. By D. W. Cathell, M.D. Fourth Edition. Enlarged. Baltimore: Cushing & Bailey. 1885.

A Clinical Lecture on the Mechanical Treatment of Pott's Disease. By Charles F. Stillman, M.S., M.D., of New York. (Reprint from the Journal of the American Medical Association, January 31, 1885.)

Review of the Drug Trade of New York for the Year 1884. Prepared by D. C. Robbins, Esq., New York.

Massage: The Latest Handmaid of Medicine. By Benjamin Lee, A.M., M.D., Ph.D., Philadelphia. (Extracted from the Transactions of the Medical Society of the State of Pennsylvania for 1884.)

The New Local Anæsthetic, Hydrochlorate of Cocaine (Muride of Cocaine), and Etherization by the Rectum. By Laurence Turnbull, M.D., Ph.G., Illustrated. Philadelphia: P. Blakiston, Son & Co., 1885.

Études sur les Scléroses Encéphaliques Primitives de l'Enfance. Par le Dr. H. Richier, Paris; G. Steinheil, Editeur. 1885.

Du Traitement Chirurgical des Néoplasmes Mammaires. Par le Docteur Emile Valende. Paris; G. Steinheil, 1885.

Des Ruptures Uterines pendant le travail à terme. Pathogénie et traitement. Par le Dr. Ladusquière. Paris; H. Laroque, Libraire-éditeur. 1884.

Le Basistrie Tarnier. Par le Docteur A. Pinard. Eleven Figures. Paris; G. Steinheil, Editeur. 1885.

Inaugural Address delivered before the New York Academy of Medicine. By A. Jacobi, M.D., President of the Academy. (Reprint from the Medical Record, New York.) 1885.

Seventh Annual Report of the Presbyterian Eye, Ear, and Throat Charity Hospital, Baltimore. 1885.

The Direct Influence of Gradual Variations of Temperature upon the Rate of Beat of the Dog's Heart. By H. Newell Martin, M.A., M.D., D.Sc., Professor in the Johns Hopkins University, Baltimore. U. S. A. (From the Philosophical Transactions of the Royal Society, Part II. 1885.)

Experimental Researches on the Circulation in Bloodvessels after Ligation. By N. Seenn, M.D., of Milwaukee, Wisconsin. (Extracted from the Transactions of the American Surgical Association. Vol. II. 1884.)

Controlling Sex in Generation. The Physical Law influencing sex in the Embryo of Man and Brute, and its Direction to produce Male or Female Offspring at will. By Samuel Hough Terry. New York: Fowler & Wells Co., 1885.

The Cure of Writer's Cramp. By A. de Watteville, M.A., M.D., B.Sc. (Reprint from the British Medical Journal, February 11, 1885.)

Annual Report of the Carney Hospital for the Year 1884. Boston. 1885.

Martin's Directory of the Druggists of the United States and Canada. 1885. Containing Lists of Druggists, wholesale and retail, etc. Advertiser Publishing Company. 1885.

Experiments upon the Heart of the Dog with reference to the Maximum Volume of Blood sent out by the Left Ventricle in a single beat, and the influence of variations in venous pressure, arterial pressure, and pulse-rate upon the work done by the Heart. By William H. Howell, A.B., and E. Donaldson, A.B., M.D. (From the Philosophical Transactions of the Royal Society, Part I. 1884.)

De l'Aphasie et de ses diverses formes. Par le Dr. Bernard. Paris: Publication du Progrès Médical. 1885.

Lectures on Diseases of the Nervous System, especially in Women. By S. Weir Mitchell, M.D. Second edition. Revised and enlarged. With five plates. Philadelphia: Lea, Brothers & Co., 1885.

AN ENORMOUS FALSE ANEURISM IN THE LEFT FLANK COMMUNICATING WITH A TRUE ANEURISM OF THE ABDOMINAL AORTA.<sup>1</sup>

BY GEORGE B. SHATTUCK, M.D.,  
Visiting Physician Boston City Hospital.

The interest of the case which I have to report lies in the question of diagnosis and in the pathological specimen to be shown subsequently.

The diagnosis lay between a vascular semi-fluid or gelatinous growth of a malignant character and an aneurism probably of the so-called false or diffused class. The opinions of those gentlemen who saw the case were pretty evenly divided between the two, and with some varied occasionally at different periods of the case. Fortunately the question of treatment was not involved, as there could be but one termination, and that a speedy one.

J. C., a currier, fifty-one years old, entered the City Hospital on February 2d. His general health had been fair, and he had continued work until eight weeks before entrance when he began to suffer from pain in the left lumbar region extending down the thigh to the leg and foot. I subsequently learned from him that he thought he had had varying pain in the back and especially in the left lumbar region nearly two years before. These pains had increased in severity. For two or three weeks he had been unable to lie in any position except upon the left side, and there was a commencing bed sore over the left trochanter. Four days before entrance the dispensary physicians, who had been summoned on account of the pains in the leg, called patient's attention to a large hard tumor between the ribs and the brim of pelvis, and advised removal to the hospital. When admitted the man was pale (almost cachectic), worn looking, and almost emaciated; there was no jaundice; the examination of the heart, lungs, and urine gave a negative result.

The tumor in the left side, according to my dictated notes in the record-book, "presented a hard mass, extending from the cartilages of the ribs above to beneath the crest of the ileum below, and from two inches to the left of the umbilicus in front to near the spinous processes of the vertebra behind. It was immovable, rather tense, smooth on the surface, though not entirely regular in outline, and dull on percussion. A pulsation, which at entrance was but little marked, became in a day or two, with improved nutrition, very noticeable both to the eye and hand, especially at two points: one in front midway between spine of ileum and pubes and two inches above Poupart's ligament, the other at the back between the crest of ileum and lower border of ribs, four inches outside of the spine. Pulsation at each point being very marked as that of an aneurismal sac with thin walls. There was no thrill or bruit, but a slight murmur over the point referred to at the side. The pulse in the femoral and popliteal arteries was feeble. There were enlarged glands in the left groin above and below Poupart's ligament." There was no apparent ascites, and no abdominal tenderness except over the swelling.

The tumor continued to increase in size and tension, the pulsation becoming more pronounced and more general, until it assumed the appearance of a good-sized watermelon lying across the left flank with an ill-defined sulcus at one part and a smooth, though not quite regular, surface; the end under the ribs being discolored and suggesting an impending slough.

February 15th I inserted a hypodermic syringe and obtained a dark bloody fluid mingled with pus. March 1st I used the aspirator; the needle being inserted one and one-quarter inches no fluid followed, but when pushed in two and one-half inches a dark-colored, quickly coagulating bloody fluid flowed through the tube, the last of which was of a brighter color. Four ounces were withdrawn, which, under the microscope, showed nothing but blood. The needle at no time gave the sense of being in a cavity.

The girth of the body across the umbilicus was frequently taken, but little value was attached to the measurements as indications of growth owing to the variable distention of the intestines by gas. February 25th, the tape showed thirty-four inches. March 5th, thirty-five and five-eighths inches.

March 9th, the photographs which I first passed round were taken, the other two being taken in the autopsy-room. The patient died on March 19th, six weeks and a half after admission, from exhaustion, having refused nourishment, and been delirious at times, for several days previously. The duration of the case was, therefore, seven weeks from the time the man's attention was first called to the tumor, three months from the time he gave up work, and nearly two years from the time he thought he first noticed pain in the back.

From Photograph taken March 9th.

The question of aneurism was entertained and that diagnosis was the first suggested. I could not, however, reconcile the history and conditions present with my experience or knowledge of aneurismal tumors. The previous history, the situation of the tumor, its apparent fixation beneath the ribs above and the ileum below, the want of any record of shock, the vagueness of previous and present symptoms except those referred to, pressure upon the lumbar nerves and their branches, the constriction across the growth, the absence of thrill

<sup>1</sup> Read at the Boston Society for Medical Improvement, March 23, 1885.

and bruit, the appearance of the patient, the absence of the sense of being in a cavity with the aspirating needle but rather in soft tissue, led me to regard with more favor, though without entire satisfaction, the diagnosis of semi-solid vascular malignant disease. A diagnosis which latterly became less tenable as the wall of the sac at its abdominal extremity became more tense and sharply defined, and the apparently enlarged glands beneath Poupart's ligament became softer. My colleague, Dr. Mason, through whose courtesy I retained charge of the case after my term of service ended, was wiser in adhering steadily to the opinion that the tumor was a sac of blood and probably a dissecting or a false aneurism.

I think such a case, viewed from the clinical standpoint, must be rare, and the books have but little to say on the subject. Stokes, in his classical treatise on the Heart and Aorta, gives by far the most satisfactory discussion of the phenomena which I have encountered, and reports one or two cases somewhat resembling this one.

Stokes, in his recapitulation of diagnostic points at the end of his chapter on "Aneurism of the abdominal aorta," lays down, among thirty-eight other propositions, the following:—

That the first development of a murmur low down in the abdomen should incline us against the diagnosis of aneurism.

That the abdominal tumors which most simulate aneurism are those whose consistence is semi-fluid.

That while the progress of an aneurismal tumor is generally from above downward, that of the solid tumor is more often from below upward. That the first appearance of pulsation, at some point low down in the belly, indicates that it is communicated to, rather than adherent in, the tumor.

It is hardly to be conceived that rupture of any other artery than the abdominal aorta could have produced a tumor of this character in this situation. To satisfy clinical record and the pathological conditions found to exist postmortem, we have then to suppose antemortem a true aneurism of the abdominal aorta situated just beneath the diaphragm in the immediate neighborhood of large nerves and nervous ganglia, attaining the size of a closed fist without much inconvenience or attracting attention, rupturing through a rent large enough to admit several fingers, without shock, and first making itself known by a swelling larger than an ostrich's egg in the left flank, which continues to grow for seven weeks at least without terminating the life of the patient, who finally dies from exhaustion after the tumor has attained the size of a large watermelon.

Autopsy, by Dr. W. W. Gannett, twelve hours after death, March 20, 1885.

Body of medium size, well developed, much emaciated. Marked lividity of dependent portions; rigor mortis present. Abdomen distended; the left half much more prominent than the right, with a soft, fluctuating area just posterior to the lateral line, above the crest of the ileum. Skin over this area dry and black. Right leg much enlarged; oedematous throughout. Diaphragm on both sides at fourth rib. Pericardium contained about ten cc. of clear fluid. Subpericardial fat considerably di-

minished in amount, of a gelatinous consistency, and of a pale saffron-yellow color. Heart of usual size. Left ventricle tolerably firmly contracted. Right ventricle and both auricles distended with partially coagulated blood. Aortic and pulmonic valves sufficient; mitral admitted tips of three, tricuspid tips of four, fingers. Valves and cavities not remarkable. Muscular substance pale in color. Inner surface, particularly the papillary portion, showed a variegated appearance, due to numerous opaque yellow spots on a pale red-brown. Pleural surfaces on both sides free from adhesion. Pleural cavities on both sides contained about ten cc. of clear fluid. Left lung retracted partly on removal of the sternum; they were of a gray color, inelastic, downy; numerous alveoli the size of a pin's head could be seen beneath the surface. Kidneys of usual size, pale, slightly yellow in color. Capsule detached with ease, leaving a smooth surface beneath. On section, ratio of cortex to medulla as usual. Glomeruli distinct as glistening points. Region of convoluted tubules and pyramids of a pale, saffron-yellow tint. Microscopically: glomeruli contained a little blood; tubules contained considerable pigment in the form of granules and discs. Bladder not remarkable.

On opening the peritoneal cavity the descending colon was found to be situated beneath the transverse colon, and extending diagonally across the abdominal cavity. The left half of the abdominal cavity was occupied by a large fluctuating mass, the upper wall of which was formed by a muscle, the fibres of which were nearly transverse. On incising this muscular wall, a cavity was disclosed, with irregular walls, filled in part with fluid blood, in part with laminated coagula, in part with soft, dark-red clots. The posterior wall was formed in part by the inner surface of the ileum, which was exposed in its upper portion and eroded; in part by the tissue lying immediately beneath the origin of the quadratus lumborum muscle. This large cavity communicated below through the femoral canal with a cavity in the upper part of the thigh, the size of the first, having a smooth wall, and coagulated blood for contents.

Just below the arch of the diaphragm the aorta was dilated so as to form a sac the size of a closed fist. The posterior wall was formed by the bodies of the last dorsal and first lumbar vertebrae, both of which were eroded about half their depth. From the anterior wall were given off the phrenics and the coeliac axis. In the lower portion of the sac, just to the left of the vertebral column, was a slit-like opening, with smooth edges, large enough to admit four fingers; it communicated directly with the large sac of blood previously described.

The aorta showed throughout, in the intima, numerous opaque, yellow, elevated patches. The oesophagus, stomach, and intestines showed nothing remarkable. Liver of usual size, pale yellow in color, opaque, and doughy.

#### DIAGNOSIS.

Fatty degeneration of muscular substance of heart. Vesicular emphysema of lungs. Blood pigment in the tubules of the kidneys. Aneurism of the abdominal aorta, rupture behind the peritoneum and

transversalis muscles, with the formation of a large false aneurism, occupying the whole lumbar region on the left side, and extending into the groin. Erosion of the vertebrae.

### THE CONSTRICTOR URETHRAE MUSCLE.—ITS RELATIONS TO URETHRAL PATHOLOGY AND TREATMENT.

BY A. T. CABOT, A.M., M.D.

BETWEEN the anterior and posterior layers of the deep perineal fascia, better known as the triangular ligament, lies the membranous portion of the urethra surrounded by the constrictor or compressor urethrae muscle.

This muscle occupies the greater part of the space between the two layers of the fascia. Its fibres, arising from the ischio-pubic rami and the tendinous parts about, run transversely across the sub-pubic arch, separating to go above and below the urethra. Besides these transverse fibres, there are others that run obliquely across the same space, and others still that encircle the canal.

Thus the membranous urethra is embedded in a muscle which, by its contraction, forces together the walls and closes the calibre of the tube. This constrictor is also known as the external or urethral sphincter and as the cut-off muscle. It is to a great extent under the control of the will and acts as the voluntary sphincter of the bladder. A brief review of the mechanism of micturition will help us to understand its functions.

As the bladder fills with urine a point is finally reached at which the internal pressure is great enough to overcome the strength of the band of elastic and involuntary muscular fibres about the urethral orifice (internal sphincter) and the urine forces its way into the prostatic urethra where its presence causes the sensation which is recognized as a "call to urinate"; its further escape is then only prevented by the contraction of the constrictor muscle.

If now no opportunity offers for micturition the compression and closure of the urethra is made more thorough by a conscious effort of this muscle, and, at the same time, the prostate closes down, pressing the urine back into the bladder, and the inclination to urinate passes away. Later, however, the urine, accumulating in still greater quantity, again enters the prostatic urethra, and, if urination is now desirable, the constrictor relaxes and the bladder empties itself.

Physiological micturition is thus easily accomplished. When, however, these parts concerned in the act are altered by disease, normal urination may be variously interfered with. An inflammation affecting the prostatic urethra renders it extremely sensitive, so that the presence in it of a few drops of urine brings on an almost irresistible desire for micturition; hence the frequency of the act which is so marked a symptom in disease of the neck of the bladder.

When the inflammation reaches to the parts about the constrictor it causes a more or less irritable condition and spasmodic contraction of this muscle. A parallel to which condition is found in the action of the sphincter an when the parts about it are

ulcerated or inflamed. The obstruction to the passage of an instrument which is usually met with at the membranous urethra in cases of chronic prostatitis is caused by, and is evidence of, this action of the urethral sphincter. A spasmodic stricture of this sort is also the not uncommon accompaniment of an inflammation affecting the bulbous portion of the urethra just anterior to the constrictor.

Now the contraction of this sphincter divides the urethra into two parts, an anterior portion, extending down to the triangular ligament, and a deep part, the prostatic portion. Indeed, the muscle in its ordinary state of tonicity makes this division, but the separation of the two parts of the canal is much more complete when it is in a state of increased contraction. And this is not a matter of interest to the anatomist alone, but, on the contrary, it is especially of importance to the surgeon, for the position and action of this sphincter exercise an important influence upon the pathological processes occurring in the canal on either side of it.

If the anterior portion of the urethra is the seat of inflammation, the contraction of the muscle protects the deeper parts and hinders the passage of discharges and the extension of the inflammatory process backward to the prostate and bladder.

When, on the other hand, the inflammation is posterior to it, the constrictor acts as a dam, and by preventing the ready escape of pus outward and by offering an obstruction to the passage of the urine, it tends to aggravate the morbid process behind it just as an anterior stricture prolongs and intensifies inflammation of the deeper parts.

From a consideration of these facts it will be apparent that when a urethritis exists in front of the constrictor muscle the passage of an instrument through it should be avoided if possible, in order that the discharges, especially when of gonorrheal character, may not be conveyed on toward the bladder. If in such a case the use of a catheter becomes necessary a preliminary irrigation of the canal may, by removing the discharges, lessen the chance of infection of the parts behind the sphincter.

In the other class of cases, when the inflammation is posterior to the urethral constrictor and is, as has been said, aggravated by the obstructive spasm of this muscle, the passage of sounds, and dilatation of it, is a most important part of the treatment; and the acknowledged value of sounds in cases of inflammation about the neck of the bladder is largely due to the stretching of this muscle effected by them.

Occasionally, in these cases, the spasm of the constrictor and the consequent obstruction to the passage of the urine is so great that while the bladder is laboring to relieve itself of its contents the pressure in the sensitive prostate becomes so excessive as to cause a pain that is scarcely to be endured. The patient strains and assists the bladder with all the abdominal pressure he can muster; until finally a few drops trickle through and the spasm slowly relaxes.

This condition of things is well illustrated in the following cases:—

CASE I. C. D., a young man of thirty-two, with chronic prostatitis of gonorrheal origin, was suffering at the time

I first saw him with attacks of pain which occurred two or three times in every twenty-four hours, more commonly at night, or when the urine had been held for a longer time than usual. In one of these paroxysms he would be seized with a severe pain referred to the rectum, or to the region between the rectum and bladder, and sometimes shooting out through the penis. This would be accompanied by an urgent desire to urinate, which, however, could not be accomplished, even by the most violent straining efforts. As he said, "it felt as if the water were blocked."

Finally, by drinking large quantities of water and walking the floor, he would gradually overcome the resistance, and the urine would begin to come, drop by drop, although still with great pain. After waiting a little longer he would be able to pass more, in a larger stream, and so the attack would gradually pass off, the pain diminishing as the stream enlarged.

These attacks disappeared immediately after beginning the systematic use of sounds, and the prostatic slowly yielded under treatment by deep injections of nitrate of silver.

CASE 11. F. S., a young man of twenty-four, was referred to me in the autumn of 1884 by Prof. Henry J. Bigelow.

In 1877 he had been attacked by cystitis, which followed scarlet fever, and lasted several years, never, in fact, having wholly left him.

When I first saw him he was suffering from frequent and painful micturition, and had a slightly enlarged and tender prostate.

At times he would have paroxysms of pain when attempting to pass water, and these were often so severe that he would crouch on the floor, and, seizing his penis, would squeeze it with all his force in the effort to obtain relief. The urine was always difficult to start, and he had "to strain to keep it going."

The meatus admitted only a No. 26 (French) bulb, which met with resistance at the constrictor muscle, and after passing this was quite firmly grasped upon its return.

With Professor Bigelow's concurrence he was etherized, the meatus was freely cut, and sounds up to No. 32 (French) were passed into the bladder without meeting with any obstruction except a sense of resistance, easily overcome, at the membranous urethra.

After this he was relieved of the paroxysms of severe pain, the urine passed readily and in a good stream, but the frequency of micturition, accompanied occasionally by some burning sensation, continued.

The histories of these patients illustrate very well, not only the symptoms consequent upon this sort of spasm, but also the great and immediate benefit to be derived from the passage of sounds and stretching of the constrictor muscle. When, for any reason, in a case of this sort, the use of instruments is impossible or unadvisable, much may be done in the way of palliation.

The benefit of heat under these circumstances is familiar to all, and frequently a hot bath or hot fomentations about the perineum will cause a relaxation of the muscle. A good dose of gin is sometimes of service, and a full opiate or a few whiffs of ether will occasionally succeed when heat has failed to overcome the spasm.

If the constriction amounts to a complete stoppage which none of the simple expedients mentioned overcomes, the catheter must be resorted to. The instrument used in these cases of prostatic inflammation should be of large size, and great gentleness should be exercised in its introduction. When the muscle is reached, steady, persistent pressure will overcome its resistance.

Besides this spasm of the sphincter urethrae, dependent upon neighboring inflammation, we see, also, at times, a spasmodic action of this muscle, brought about by purely nervous causes. A familiar example of this is the stoppage of urine, which occurs after an operation or during an inflammatory condition about the anus.

Utzmann<sup>1</sup> says: "Not seldom we find spasmodic contractions in both rectum and urethra at the same time, when the lesion can be detected in

but one of these. Thus we find spasm of the rectal muscles in cases of catarrh of the neck of the bladder and *vice versa*. This is explained by the fact that both regions are supplied by the same nerves, namely, the middle and inferior hæmorrhoidal."

Irregularities in the action of the constrictor may also depend upon psychical causes: Thus, some people cannot urinate in the presence of others, and, at times, the muscle seems to be affected with a really choreic condition which causes an uncertainty of micturition, that has been well described by Paget<sup>2</sup> as "stammering with the urinary organs."

Paralysis of this sphincter is sometimes the result of disease or injury of the spinal cord and is ordinarily associated with paralysis of the muscular walls of the bladder. The natural obstruction in the urethra due to the elasticity of the tissues is usually enough to cause the bladder to become distended, and, unless the urine is regularly drawn, the overflow finally forces its way through and escapes as a constant dribbling.

Occasionally incontinence occurs in a seemingly healthy man without loss of the expulsive power of the bladder. This seems to be due to a direct failure of the constrictor, and may be usually remedied by a tonic course of treatment with the use of electricity, which may be applied either from pubes to perineum, or, better, with one electrode in the membranous urethra and the other upon the pubes. The incontinence of childhood arises from inattention to the call to urinate, to which is often added an increased sensitiveness of the prostatic urethra, rather than from any incompetence of this muscle.

Finally, in regard to the effect that the position and action of the constrictor has in modifying our methods in the local treatment of urethral disease,<sup>3</sup> The normal tonic contraction of this muscle is usually of sufficient strength to prevent the passage through of an ordinary urethral injection unless it is thrown in with considerable force, or unless anesthesia has caused relaxation.

In the use of injections for gonorrhœa, however, it is not uncommon, as an additional safeguard, to still further compress the deep urethra by causing the patient to sit on a folded towel or upon the arm of a chair during the injection. This method is objectionable in that the bulbous urethra, which is a favorite lurking-place for gonorrhœal virus, is also compressed by this procedure, and the injection fluid is thus prevented from entering that portion of the canal where it is most needed.

It is a better plan, therefore, instead of using an ordinary urethral syringe, to make the injection through a small, red rubber catheter, introduced as far as the bulb of the urethra. The constrictor is of sufficient strength to turn the fluid back and to cause it to escape alongside of the catheter, and the whole canal anterior to the muscle is thus thoroughly washed by the medicated solution. Care should be taken, of course, not to push the catheter through the sphincter, and this may be guarded against by marking the catheter at a distance of six

<sup>1</sup> Ullrich's lectures.

<sup>2</sup> For a full consideration of the question of local treatment in the urethra, see Pyuria, by Utzmann, translated by Dr. Platt. New York: D. Appleton & Co. 1884.

<sup>3</sup> Pyuria. See below.

to six and one-half inches from the point and never allowing this mark to pass the meatus.

When now the injection is to be applied to the prostatic urethra it must be conveyed through the constrictor by means of a metallic catheter, of which the best is that devised by Ultzmann. The end of this instrument should be placed just beyond the sphincter, and the fluid, when thrown in, thus washes out the prostate and flows on into the bladder, where, if non-irritating, it may be left, or from which it may be withdrawn by slightly advancing the catheter. To determine when the point of the catheter is in the prostrate is ordinarily easy to one accustomed to make these applications, for the sensation of a slight resistance at the constrictor is easily perceived, and, as soon as this is passed, the instrument is in correct position. In case of doubt, the catheter may be advanced till it draws water and then withdrawn into the prostate.

In conclusion, I would say that I have endeavored not to overstate, and do not think I have overestimated, the importance of this constrictor muscle in relation to the pathology and treatment of the inflammations of the urethra and neck of the bladder, and I believe that a correct appreciation of its action is of the greatest importance for the proper application of local treatment to these diseases.

#### REPORT OF A CASE OF MONOMANIA.<sup>1</sup>

BY E. S. BOLAND, M.D.

Miss X. consulted me in September, 1883, for what she recognized as a third attack of insanity. Aged thirty-one. She is the youngest of five children. There is no insanity in the family as far as known. She is a Catholic. Naturally amiable, sociable, and intelligent. A graduate of one of the city grammar schools, she declined a proposed normal course and began to learn dressmaking with an older sister.

She is of rather slight build, but is fairly well-proportioned and has pleasing features. Her hair began to turn in her teens and is now quite gray. Menstruation began about the age of twelve, but was always scanty and the periods painful. At fourteen or fifteen there was amenorrhea for a year or more, for which she was treated locally with some benefit. With this exception her general health has been good except during the two former attacks, which shall be referred to later.

When she presented herself she had for some years been employed as a saleswoman in a large dry-goods house. Beginning to feel unequal to her work she took a vacation, but received no permanent benefit. She complained of failing general health and inability to fix her mind on her work. She had an involuntary and irresistible impulse or conception to repeat every act, word, or thought five times. This occupied all her waking hours, to the exclusion of almost every other mental operation.

This symptom was present in both former attacks and she has learned to fear it. The first of these attacks she recovered from at home in four or five

months, the second attack lasted over a year and was recovered from in the Boston Lunatic Hospital. Along with the imperative repetition of everything in series of fives there was complete menstrual suppression and dreamless sleep. Both these symptoms had again recurred. She knew too well their significance and was in dismay at the prospect of months of suffering before her. There was some loss of flesh, poor sleep, and great mental suffering. She knows the absurdity of her counting and felt that it is a great annoyance to her family and yet she was totally helpless to resist it.

Hospital treatment was advised but was not acted on and she was treated at home. A liberal diet, wine, and rest was ordered, and iron quinine and strychnine in tonic doses was prescribed and various combinations of sedatives given for the relief of her broken sleep.

After several weeks of this treatment, no improvement could be seen. In fact she seemed to get worse. The counting continued on every occasion, the sleep was poor, appetite deficient and irregular, and from standing and debility her feet and ankles became edematous at night.

Still, her ordinary intelligence was not markedly affected, her memory was good, her hope of recovery persisted, and she was keenly aware of her unfortunate and troublesome condition. Hospital treatment was again urged. The friends would gladly have sent her to the hospital, but it was then crowded and they refused to have her sent to a State hospital. She would not go voluntarily, as she dreaded the surrender of her own way, which commitment implied. She was ordered to bed, and no evidence of heart or kidney trouble being found, the treatment before instituted was continued, both as to medicine and diet. For three months she gradually grew worse. She ate irregularly, sat up in bed, counted, and compelled the rest of the family to count, or repeat anything said or done. If she moved her hand or her body once she had to repeat the act five times. If she swallowed saliva once she had to do so five times. She had grown so persistent and noisy that she was kept in an attic room. Here, if she heard the front door closed, she would give the family no peace until it had been closed five times. When I called and took her pulse or examined her tongue she would manœuvre to have the operation repeated five times.

With failing general health the dominant idea grew stronger. She resisted noisily every effort for her care. Her toilet, her meals, her bedmaking, etc., became occasions of great trouble to her family. She wet the bed, refused food except at night, and kept an elderly aunt, who had the immediate care of her, so busy counting and repeating acts, that she was almost worn out. She opposed any disturbance or change in her clothing, etc., and grew exceedingly dirty and disagreeable-looking. The family were worn out by her exactions and the neighbors complained to the police of the noise she made.

She was conscious of her state and actually loathed it, showed mortification at being seen in such a plight, but was so inert bodily and mentally she would not try to help herself. There was no turning against any of the family and she realized what a nuisance she was at home.

<sup>1</sup> Read before the Boston Medical-Psychological Society, December 18, 1884.

At this time, May, 1884, a vacancy occurring in the Boston Lunatic Hospital, she was regularly committed. When told she was to go to the hospital she protested, but made less trouble than was expected. She was able to walk up to her room with some help and was put to bed.

She still counted, sat half erect in bed, and was opposed to any change in room, bed, attendants, etc. She rather protested against toilet requirement, but less so than at home; in fact, was never noisy after admission. She was rational in her talk and very grateful for what was done for her. Extra diet, tonics, and some sedatives were used, and, as soon as possible, she was made to sit up and go out, but this was not until she had been in the hospital a month. About this time her reflexes were taken, and she wanted the tests made five times. When gotten up she always sat bolt upright in her chair with a hand on each knee, and her face as set and body as motionless as an Egyptian deity in stone. To propose another place or chair was to distress her very much, and she would always protest and say: "Just wait a while till I get better."

The tormenting *fices* still controlled her thoughts and actions. It differed from the self-imposed posture, phrase, or trick of the hysterical or demented patient. She realized its absurdity and regretted her submission to it, but is apparently as powerless to resist it as is the epileptic to suppress his fit or automatism. Ordinarily ladylike and stylish she was now negligent of her appearance, would not use a toothbrush and would sit or go out in a wrapper.

There was a slight general improvement for some months but she was all the time sensitive to any change and shrunk from notice. During October there was a gain in weight and the acne disappeared from her face and her sleep was better.

November 7th, she suddenly felt the cloud lifted and found herself in excellent spirits. The counting was suspended and she was happy as a child. This respite lasted almost two days when she dropped back again, but not so bad as before.

At this date she has almost regained her usual weight, looks bright, talks readily and well, and goes to chapel but does not yet read or work. She begins to dream at night as is her habit in health. She still has to count some at times. She has all through this attack evinced a desire to wait rather than work for her recovery, which she seems never to have doubted would come and which we think will be complete in a few months.

The case might be regarded as simply one of hysterical mania in a girl of a degenerative type, for there has been recurrence and there is presumably imperfect sexual development and premature gray hair, etc., but the persistence of the dominant symptom — involuntary counting — hardly admits of being classed among the well-known and shifting vagaries of the hysteric. That she is wilfully indulging this freak of counting I do not believe. She does not parade it, regards it with disgust, and shows genuine pleasure at its disappearance. Viewed in any light these features of her case will strike the observer:

Her type of constitution; three attacks of gradually increasing severity in which these three

symptoms recurred: amenorrhea, dreamless sleep and imperative impulse to count in *fices*; mental and physical inertia; loss of thought-control; dread of change; hope of recovery.

## REPORT ON CARE OF THE INSANE.

BY WALTER CHANNING, M.D.

### SUICIDAL PATIENTS IN INSANE HOSPITALS.

DR. SAVAGE writes<sup>1</sup> of the dread that the public have of the commission of suicide. He himself thinks that the consideration of how suicides can best be avoided in lunatic asylums should be secondary to the care of curable cases.

In the Bethlem Asylum, of which he is superintendent, from twenty to thirty per cent. of the patients are described as suicidal, on admission. If this large number were to be placed under inspection the asylum must cease to exist as one in which patients have separate rooms and are treated in a homelike way. The number of actively suicidal patients, however, probably does not exceed five per cent.

Among the most dangerous are those patients with hallucinations of hearing, those who are persecuted, or whose relations are persecuted, those with profound mental misery, etc.

The "persecuted" man is often more at peace if left in a room by himself, and often, also, young, plastic girls, who will be made more suicidal by association with others. Even patients who have attempted suicide, and who come of suicidal stock, can best be relieved from the thought of suicide, "though with some risk," in single rooms.

Dr. Savage says he does not consider constant watching of benefit to the patient. Patients have often told him, that when constantly watched, they felt as if they were dared to do a thing, and naturally set themselves to work to evade their tormentors.

It doubtless gives the superintendent a feeling of security to know that a patient is constantly watched, but the chances of recovery, though attended with greater risk, will be better in single rooms.

When a patient is admitted to the Bethlem Hospital with "suicidal" against his name, Dr. Savage puts him for a few nights in strong clothes and strong sheets in a single room. He examines the patient to decide whether this is necessary, and very often he accepts the statement of the patient, that he will exercise self-control. By encouraging self-reliance the patient very generally gets well, which he believes would not be the case if he were not trusted.

### GERMAN IDEAS OF INSANE-ASYLUM BUILDING AND MANAGEMENT.

Dr. Hasse, director of the insane asylum at Königsbutter, in the Province of Brunswick, writes entertainingly on this subject.<sup>2</sup>

<sup>1</sup> Constant Watching of Suicidal Cases. By George H. Savage, M.D., Journal of Mental Science, April, 1884.

<sup>2</sup> Klinische über Irrenanstalten. Von Med. Rath Dr. Hasse. Allg. Zeitschrift f. Psychiatrie, II. Band, I. Heft.

First, he describes the building of an addition to his institution for seventy-four patients. He traveled through Germany, Switzerland, and England for the purpose of getting suggestions as to buildings and finally decided to put up four pavilions.

These pavilions are each separate and entire by themselves, and a short distance from the parent institution, yet they are near enough to be easily managed. Everything is open and free in them, so that patients can go in and out as they please.

The buildings are of stone, after an agreeable style of architecture.

In the basement are the bathing arrangements, in the men's department there being a swimming-basin.

The pavilions for the men and women of the first and second classes have four single rooms on the first story. These rooms open into large rooms, which are the dining-room and parlor, the latter room being connected by large doors. The parlor for the men contains a billiard-table, and that for the women a grand piano. There is also a room for employees in this story. In the second story there are more single rooms for patients and an attendant.

The arrangements in the pavilion for the patients of the second and third classes are quite different in regard to sleeping and day rooms.

In these pavilions the patients pass the day in the first story, and sleep in the second. Each dining-room has a capacity for twenty-five patients and two attendants. On each side are large halls for reading, conversation, amusements, etc. Connected with these halls is a room with two beds for any case of sudden sickness during the day.

Dr. Hasse gives quite a glowing account of the Morning-side Asylum, yet he is honest in his criticisms, and says it has its weak side, like everything else in the world. In several of the buildings the corridor is in the middle, and so shut in by the rooms on each side that it can only be lighted by light from above. One could become melancholy with such surroundings, if not already so.

The single rooms are all too small, and the buildings for the rich patients are poorly situated.

The infirmary is remarkably complete in all its details, being provided with everything necessary for bodily sicknesses.

The Englishman loves to decorate and carpet every nook and corner of his house, rather more than is necessary according to the German idea, but this infirmary presents a "luxurious simplicity."

The Morning-side Asylum has had the reputation of having reached the highest point of development of the "open-door" system, but this is an error. Perhaps the only asylum which can lay claim to having reached this point is that at Lindsay, in Glasgow. Even here, however, the system is not absolutely carried out. In the first place the wards at Lindsay are not opened until 10 o'clock, and are closed again at 5 o'clock. At 7 o'clock all of the patients are put to bed. " . . . The wards are all opened — yes; but those patients who for one reason and another are not considered in a proper condition to associate with the others will be locked in their rooms in their own wards."

These exceptional cases destroy the principle of an open-door system, in the sense of being open to every patient.

In the asylum at Königsutter the open-door system is also available for all such patients as are fit to be trusted; further than that they do not go. Both at Lindsay and Morning-side the open-door system is used much more extensively than in most German institutions.

Dr. Hasse closes his remarks on the open-door system as follows: "When, in London, I talked with Crichton Browne, one of the Commissioners in Lunacy, in regard to the open-door system, as it was now being forced (*poussée*) in Scotland, he laughingly shrugged his shoulders. Then I also do." "Die Realame darfnoch nirgends fehlen."

#### INSANE INSTITUTIONS OF BOHEMIA.

Dr. H. Dagonet, the medical head of the St. Anne Asylum for the Insane in France, gives a clear description of a late visit to the new Bohemian asylum at Dobran.<sup>3</sup>

Bohemia, the important Austrian province, contains a population of 5,500,000, of whom two fifths speak German. There are twenty-two hundred insane patients inclusive of idiots, which gives about one lunatic to twenty-five hundred inhabitants. The French Department of the Seine, which includes Paris, has a proportion of about one to three hundred, a difference easily explained by the different character of the people.

There is at Prague an institution for one hundred idiots, and others are boarded out in families.

The principal lunatic asylum of Bohemia is at Prague, and contains eleven hundred inmates. Connected with this is a department for incurables, at Kosmanos, a few miles distant, containing five hundred patients.

The new asylum at Dobran has been opened four years and a half, and is on the Pilsen and Eisenstein railway. It is constructed on the principle of separate pavilions, and cost 3,300,000 francs. Three principal detached buildings form the front of the asylum, the middle one being used for administrative purposes, and one on either side for the quiet men and women. Behind these are buildings for the partially excited, and other buildings for the excited, the sick, and suicidal. There is a building for dirty paralytics; a farm for the workers; a pavilion for the divers professions and trades, and buildings for the baths, laundry, employees' families, and an isolated building for contagious diseases. Most of these buildings are connected by corridors. The building for the quiet has the paying patients on the first floor and the paupers on the second floor.

Each story has two dormitories for ten patients, separate chambers, cabinets, bathrooms, parlors, etc. The chambers open on a corridor, in which the patients walk. In some ways convenience is sacrificed to architectural effect. The asylum is placed on a high, barren hill, which is very inconvenient and calculated to depress the patients.

Dr. Pick, the medical director of the institution, is a well-known alienist, and may be selected to take the chair of psychiatry at the University of Prague, which has been refused by Dr. Krafft-Ebing.

<sup>3</sup> Une Malade à l'Asile d'aliénés de Dobran. Par M. le Dr. H. Dagonet. *Annales Médico-Psychologiques*. Forty-third Year, No. 2, 1885.

Dr. Pick has under him a steward, steward's assistant, and clerk, to look after the business details.

One family at Prague has charge of the catering for the different hospitals and asylums of Bohemia, and the cook at Dobran is a member of this family! A certain fixed amount is paid for each patient's ration, and there is a special tariff for extra diet ordered by the physicians.

Under the medical director there are three medical assistants, who are paid only 1,200 florins annually. There is one nurse to seven or eight patients. Restraint is used as little as possible. Camisoles and locked gloves are used in the rarest instances. Consultations are allowed with outside physicians at the request of the patient's friends. Within forty-eight hours of the admission of a patient, the court must be informed and an official visit the patient.

The insane of Bohemia principally have quiet forms of insanity. Aside from puerperal mania, the cases among women are chiefly of melancholia. Among men, insanity from alcohol and general paralysis are the chief forms observed. The proportion of the former is about twenty in one hundred, and there are twenty-five cases of general paralysis in one hundred among the men, and eight in one hundred among the women. The duration of general paralysis is longer in the female cases than the male. Seventy patients in one hundred are occupied. Paraldehyd is used instead of chloral, in doses of six to eight grammes. Morphia and hyosciamine are used hypodermically, in doses of one to three milligrammes. Baths of two hours are employed, and the douche is used as a means of moral treatment. "A woman resists no more after she has had the douche, Dr. Anton (the assistant) told me: I do not believe this simple means would suffice in our asylum!"

#### CONDITION OF THE EYES OF THE INSANE.

Drs. Wigglesworth and Bickerton<sup>1</sup> have recently published their conclusions on the condition of the eye in the insane. With the proviso that it is necessary to draw a clear line of distinction between the disease known as general paralysis of the insane, and other forms of insanity, they find (1) that in insanity proper (including all other forms than general paralysis) changes are found in a small minority of cases. Making allowance for changes depending upon associated constitutional conditions, errors of refraction, etc., the number of cases in which a connection between the mental (cerebral) state and the accompanying change in the fundus oculi can be so much as suspected is very small.

As a corollary from this it may be said

(2) That in insanity proper no connection can be traced between the condition of the fundus oculi and the patient's mental state.

(3) That in the majority of cases of general paralysis the fundus oculi presents a perfectly healthy appearance.

(4) That in a minority of cases clear and precise lesions are found.

(5) That these lesions fall into two main classes, the one tending in the direction of slight neuritis, the other in that of atrophy.

(6) That in the former class the affection declares itself as a hyperæmia of the discs, the edges being softened and indistinct, so that in some cases they can be traced with difficulty or not at all. These conditions tend to be replaced by atrophy, if the patient live long enough, and complete disorganization of the nerve may take place. The changes are essentially chronic.

(7) That, though atrophy of the optic nerves may thus succeed to a slight chronic interstitial neuritis, it is also not infrequently primary *at the disc*; the atrophy may be complete, the patient becoming quite blind.

(8) That the pathological basis underlying the appearances of a slight neuritis may be broadly characterized as a tendency to overgrowth in the connective elements of the nerve; the trabeculae not only getting greatly hypertrophied, but the neuroglia corpuscles becoming very large and numerous; these parts thus grow at the expense of the nervous elements, which subsequently atrophy.

(9) That in cases of primary atrophy the pathological appearances eventually reached, though somewhat similar, may possibly take place in the reverse order *at the disc*; the nerve fibres being the first to dwindle, and the fibrous elements, trabeculae, etc., subsequently taking on increased growth.

(10) That in a considerable proportion of the cases, in which atrophy of the optic discs is met, spinal symptoms are prominent in the disease, these symptoms pointing in the direction of posterior or lateral sclerosis of the cord; but that the connection is by no means invariable.

#### CHANGES IN THE URINE IN FASTING INSANE PERSONS.<sup>5</sup>

Herr Tuzek has made some investigations in this direction in two patients who went without food for some time. The first patient, who was thirty-two years of age, fasted for twenty-three days. During eight days nothing was taken into the stomach, and during the remainder of the time only water. The second patient, who had delusion of poisoning, fasted for twenty-eight days, during fourteen of these days taking nothing.

In the latter case the urine excreted in the twenty-four hours amounted to only nine grammes. The specific gravity increased with the increased concentration, grew less at a later period, then rose again. Indican was absent during the gradual diminution in the amount of the urine and appeared only when food was again taken.

The amount of albumen excreted during fasting, as shown in these investigations, is very small.

The loss of weight in the fasting is particularly due to the diminution of water.

According to Herr Tuzek's investigation, the proper way to prevent great loss of weight in fasting subjects is by warmth and rest rather than by forced feeding.

The above remarks are interesting as bearing on the subject of forced feeding of the insane, to which attention was called last year in this report.

How far we may be inclined to follow the suggestions of late German writers in administering food is for each one to settle for himself. Undoubtedly, feeding has been often pushed too far and at any

<sup>1</sup>On the Condition of the Fundus Oculi in Insane Individuals. By J. Wigglesworth, M.D., and T. Bickerton, F.R.C.P., Brain, July, 1884.

<sup>5</sup>Centralblatt, July 15, 1884.

rate carried out empirically, but we shall hesitate for some time before we allow two, three, and four weeks to elapse without giving even a small quantity of water.

#### BLOOD OF INSANE PERSONS.

Dr. Macphail has made a very thorough study of this subject at the Garlands Asylum, Carlisle, of which institution he is the assistant medical superintendent.<sup>6</sup>

In examining the blood for clinical purposes there are three points to be considered: (1) Its richness in corpuscles. (2) The richness of the corpuscles in hæmoglobin; (3) The amount of water diluting the corpuscles.

For determining the richness of the blood in corpuscles, Macphail used Dr. Gower's hæmacytometer, and for ascertaining the amount of hæmoglobin, the hæmoglobulinometer.

The total number of his observations was four hundred and twenty.

Dr. Macphail's general conclusions, which we have only room to present here, were in part as follows:—

(1) While there is no evidence to show that anemia is in itself a cause of insanity, yet an anemic condition is often associated with mental disease.

(2) The blood in masturbating patients is deteriorated to a marked degree.

(3) The blood is below the normal standard in general paralysis, and most so in the active and completely paralyzed stages.

(4) While there is a deficiency in epileptics, it is not so marked as in dementals at the same age.

(5) Prolonged and continuous doses of bromide of potass. do not cause deterioration in the quality of the blood.

(6) The blood of the average number of patients is deteriorated on admittance to the asylum.

(7) In patients who recover, it is not below normal on discharge.

(8) There appears to be a close connection between gain in weight, improvement in quality of blood, and mental recovery.

(9) Improvement in mental condition is most marked under tonic treatment.

(10) The four tonics which proved most efficacious in restoring the quality of the blood were in the order named: (a) iron, quinine, and strychnine; (b) iron and quinine; (c) iron alone, and (d) malt extract.

(11) Arsenic proved of little value as a blood-tonic and observations with cod-liver oil and quassia were not satisfactory.

(12) The close connection which exists between improvement in the quality of the blood, increase in weight, and mental recovery, the converse which exists in cases of persistent and incurable dementia, and the marked improvement under the use of remedial agents, show that this line of clinical research, more especially with reference to the curative treatment of the insane, should have more attention paid to it than has hitherto been the case.

#### DRUGS IN THE TREATMENT OF INSANITY. OPIUM.

The use of this drug in treating the insane has been alternately extolled and condemned. Many of the older insane-hospital superintendents have used it through thick and thin, passing through the chloral, bromide of potass., hyoscinamine, and other sedative waves, comparatively untouched. The utility of small doses of opium or morphia in melancholia has been generally recognized, and this plan of treatment pursued when the drug was used in no other way.

Within the last year or two, however, the opium treatment in all forms of insanity has shown a new lease of life and Dr. H. Engelhen, among others, speaks of it in the highest terms.<sup>7</sup> Narcotics to overcome the condition of pain of all kinds are of the highest importance, and opium is the first and best of all of these.

There have been many failures in the hands of physicians who have seen little of mental diseases and do not carry out the opium treatment thoroughly.

Schille, at Ellenau, has had great success with injections of morphia, more particularly in cases of melancholia. The injection plan of morphia has a certain amount of fashion and prestige about it, but is not so well adapted for cases in private practice. Neither is morphia so successful in overcoming mental and physical irregularities as opium with its numerous alkaloids, and Dr. Engelhen gives up the injections in hospital treatment. The advantage of opium consists largely in its easily recognized tonic and nutritive properties.

In some cases improvement immediately takes place, in others it is much protracted. Many cases have been recorded where improvement was marked from the first dose. Dr. Engelhen has seen no case where improvement has not taken place.

The dose should be great enough to produce a light but decided narcotic effect. A dose of this sort lessens the neuralgic pain, so often present, as well as the feeling of weariness.

In most of the cases of the cerebral neuroses, two to three tenths of a gramme given daily in divided doses will be a sufficient quantity. In some cases of extreme violence or very intense melancholy larger doses for a short time may be necessary.

When the proper sized dose has been found the treatment must be persisted in until complete recovery is nearly reached, and then the doses can be diminished gradually, great care being exercised in so doing. First, the dose may be lessened by a quarter or a third, the patient being then carefully watched for a period of eight days. If no ill effect is observed, a slight further reduction may be made. If at any time a relapse is observed, the dose must be increased to the next highest dose.

Small doses are of no effect. Large doses given twice daily are alone of any service.

With great excitement the opium will not produce sleep until it has produced an effect on the brain irritation. In such cases sedatives, such as chloral, given for a few nights in moderate doses, may be necessary.

<sup>6</sup> Allg. Zeitschrift f. Psychiatrie, 11 Band, 1 for Heft.

<sup>7</sup> Clinical Observations on the Blood of the Insane. By S. Rathcliff Macphail. Journal of Mental Science, October, 1884, and January, 1885.

An equally strong endorsement of the virtue of morphia is found in the recent observation of Auguste Voisin.<sup>8</sup> He has persisted in the opium and morphia treatment of insanity since 1867. His success was first interfered with by the obstinate vomiting, but learning from Roller that, notwithstanding, the dose must be increased, he was ultimately successful. He has treated mania, melancholia, criminal insanity, and moral insanity with good results. He uses the hydrochlorate of morphia hypodermically.

In the initial dose, he does not exceed one to three milligrammes. Light cases are sometimes relieved by a daily dose of five or six centigrammes, but in other cases the dose has to be increased to seventy centigrammes a day.

The influence of the medicine is shown by redness of the face and conjunctivæ, nausea, vomiting, general sensation of heat, lassitude, sleep, loss of weight, diminution of arterial tension. Later the color improves and there is a gain in weight.

The presence of a congested condition of the cerebro-spinal system presents an absolute contra-indication to the use of morphia, as well as epilepsy and general paralysis.

#### ERGOT.

Dr. Nebel<sup>9</sup> has recently been led to try ergot in a somewhat new way after the suggestion of Dr. Luton, in the *Bull. de Théor.* c., p. 254, 1881, who gave his patients a mixture of tincture of ergot and phosphate of soda, which he called "mixture exhilarans," because of its similar effect to laughing-gas.

The writer records his observations for the purpose of giving renewed vigor to the use of ergot in cases of insanity. He regards ergot as a valuable drug in arterial and blood changes, exerting a considerable influence on the cerebral circulation.

He used in his experiments a mixture of tinct. secale cornu 4.0, natii phosphor 1.5, aque 15.0, giving this amount daily.

The results of his observations to a certain extent confirm those of Dr. Luton. The mixture often produces a condition of exhilaration, similar to that of intoxication, within a period of one hour. In most of his cases there was improvement, which seemed to be decided in character, and many of these cases were ones in which no change had taken place for a long time.

Dr. Jaekel, in a note, or postscript, to Dr. Nebel's paper, details briefly the conclusions of Dr. Adam, interne d'asile d'aliénés de France.

Dr. Adam gave only a few single doses in each case, fearing the effects of the intoxication produced. His cases were principally of melancholia.

He concludes: (1) That the mixture exhilarans can in certain cases modify condition of depression, but only for a short time and is not to be entirely relied on; (2) Laughing attacks (described by Luton) he has not met. (3) Doses of nine grammes of the tincture of ergot and two and seven-tenths grammes of phosphate of soda would produce vomiting and bad feelings and

are too large. (4) It is to be supposed that the long-continued use of the mixture would produce injurious effects.

The two latter conclusions are directly opposed to those of Nebel, who gave large doses for months at a time, and never saw any indication of ergotism as well as no interference with menstruation.

#### PARALDEHYD, NITROGLYCERIN, AND JAMAICA DOGWOOD.

Dr. J. B. Andrews,<sup>10</sup> superintendent of the Insane Asylum at Buffalo, New York, presented this interesting paper at the meeting of insane-hospital superintendents in May last.

His experiments were carefully made, and largely with the aid of the sphygmograph.

PARALDEHYD, with which we have become familiar during the past year more especially, was first introduced to the Italian medical profession, by Cervello, of Palermo, and in September, 1882, was reported on, at a meeting of the Italian Medical Association, by Morrello and Bergesio.

It is formed from an aldehyd, by the action of an acid. Its symbol is  $C_6H_{12}O_3$ . When acted on by chlorine, it is said to be converted into chloral.

It has a pungent, unpleasant taste (far worse than chloral). It is miscible in eight times its bulk of water.

Its use is that of a sedative and hypnotic.

Dr. Andrews gives nine cases in which he used paraldehyd experimentally to ascertain its physiological effects. In these cases one to three drachms was the size of the dose. The result showed that even large doses were not capable of producing with certainty a hypnotic effect.

The number of clinical cases in which the drug was prescribed was ten. In five of these cases the results were satisfactory; in the other five no benefit was derived.

The effect of a large dose was like a stimulant in a narcotic dose. When sleep was produced from a small dose, it was pleasant and natural.

The effect of the medicine was at its height in from thirty to forty-five minutes.

Paraldehyd is antiseptic like chloral.

Dr. Andrews concludes that, while this drug possesses undoubted hypnotic powers, its bad taste, the large amount of water needed to dilute it, and its similarity, but inferiority, to other hypnotics, contra-indicate its general use.

NITROGLYCERIN, OR GLOXOIN. The theory of the action of this drug is that it reduces arterial tension by paralyzing the vaso-motor nerves, and thereby dilating the bloodvessels.

Dr. Andrews first tried gloxin to ascertain its physiological effects, and then gave it to demented with cold extremities, and epileptics. The dose he used was from three minims upward.

The conclusions from his experiments were: (1) they sustain the theory given of its action; (2) it has no beneficial effect in dementia, as claimed, other than to temporarily relieve the congestion of the extremities; (3) in many cases of epilepsy it has a positively injurious effect.

JAMAICA DOGWOOD (*PISCIDIA ERYTHRINA*). In

<sup>8</sup> *Leçons Cliniques sur les Maladies Mentales*, 1883. Jour. Am. Med. Association, vol. III, p. 247.

<sup>9</sup> *Ein Beitrag zur Wirkung der Ergotins bei Psychosen*, Hyster. Band. 2ter Heft. 1884.

<sup>10</sup> Report on New Remedies, By J. B. Andrews, M.D. American Journal of Insanity, October, 1884.

880 Dr. James Scott published in the *Therapeutic Gazette* a few notes on the use of this drug as a substitute for opium in the treatment of a class of cases characterized by excitement and restlessness, which morphia and other preparations of opium have failed to control. The effects, as described by him, were remarkable. In some cases sleep was produced. On awaking, the patients were comparatively quiet and tranquil. In more severe cases it was necessary to repeat the dose until the narcotic effect was manifest.

Dr. Andrews concludes, from his own experiments, that dogwood is a hypnotic of uncertain power, and that to gain any benefit it must be given in larger doses than recommended by the makers, from a drachm and a half to two drachms. In such doses nausea is frequently produced. It is not a remedy to be relied on in insanity, but may prove useful in some nervous and hysterical cases where opium is contra-indicated.

THE LENGTH OF THE TIME OF REACTION (OR REFLEX ACTION) IN THE ACOUSTIC HALLUCINATIONS OF THE INSANE.

Guicciardi and Tanzi<sup>11</sup> have recently published an interesting paper on this subject. Hallucinations of hearing have been chosen because of the great clearness and brilliancy with which they are repeated, and their subjects are often possessed of a considerable degree of intelligence.

The reflex arc can be divided into five portions: (1) peripheral apparatus of sense; (2) the centripetal avenue; (3) the portion of conscious elaboration; (4) the centrifugal avenue; (5) the peripheral apparatus of motion. In these tracks variations occur, which are incomparably more numerous in the conscious portion than any other, as in the latter are comprehended perceptive and motor determination, these being affected by attention and will.

The experiments made by the writers were upon both sane and insane individuals, for the sake of comparison. Of the latter, six were men and eight women, most of them being cases of persecutory and ambitious paranoia. Fifty observations were carefully made with the cronoscope, the results being expressed in minimum and maximum groups of figures. From these observations it was found that reaction was more intense, more perfect, with a greater degree of attention, than in sane individuals in the earlier observations. These conditions disappeared, however, as outside interruptions and distractions increased.

The writers were led to conclude that the concrete sensation of a given object is formed either without any centripetal action of the peripheral sensorial apparatus, or by an action of the latter which is inadequate to the forming of an image.

There takes place in the first case a hallucination purely perceptive, which is nothing but an image, unemotional or mental, reproduced with an uncommon degree of intensity, and hence of reality (morbid irritability of the sensorial centres of the cerebral cortex, analogous to that which epilepsy of cortical origin produces on the motor centres).

In the second case the hallucination partakes of the nature of an illusion, and depends on the erroneous interpretation of a peripheral stimulus.

Jolly found in five cases a hyperaesthesia of the acoustic nerve, which enabled Brenner to subject hallucinated persons to an advantageous treatment with electricity.

Guicciardi and Tanzi end their paper by saying that "however little importance the promptitude of reflex action may have as an expression of the degree of intelligence preserved, nevertheless, the presence of the promptness in cases of paranoia confirms the generally accepted belief that in this form of insanity there is no tendency to a real intellectual weakening."

## Reports of Societies.

### PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M.D., SECRETARY.

MARCH 23, 1885. The President, Dr. F. W. DRAPER, in the chair.

Dr. GEORGE B. SHATTUCK reported a case of

ENORMOUS FALSE ANEURISM OPENING FROM THE ABDOMINAL AORTA.

Dr. W. W. GANNETT described the appearances found at the autopsy. There was an aneurism of the abdominal aorta just below the diaphragm, the size of a closed fist. From its anterior surface the two phrenic arteries and the coeliac axis were given off. Its posterior wall was formed by the bodies of the twelfth dorsal and first lumbar vertebrae, which had been eroded to half their depth.

The aneurism had ruptured, by a slit-like opening wide enough to admit the tips of four fingers, into the tissues posterior to the peritoneum, dissecting off the transversalis and quadratus lumborum muscles, on the left side, from the deeper-lying muscles, pressing these forward and forming an extra peritoneal cavity the size of a watermelon, which was filled in part by laminated, pale coagula, in part by dark, soft coagula and fluid blood. In other words, a false aneurism, or hematoma.

The blood in its course had separated the iliacus from the left ilium over its upper third, and there was considerable erosion of the bone. The blood had extended through the femoral ring on the left side into the tissues of the upper part of the thigh, where there was a cavity the size of a fist, with smooth walls, and filled with coagulated and fluid blood.

The tumor formed by this extravasated blood occupied about half of the cavity of the abdomen.

The descending colon had been pushed over to the right side of the abdomen, and the left kidney lay transversely on a level with the spleen.

Dr. J. C. WARREN made some interesting remarks

ON THE HEALING OF ARTERIES AFTER LIGATION,

and showed specimens.

Dr. A. T. CANOT read a paper entitled

<sup>11</sup> Il Tempo di Reazione negli allucinati acustici. Paranoici. Del Dottor Giuseppe Guicciardi ed Eugenio Tanzi. Rivista sperimentale di Freniatria. Anno X., Fascicolo IV., 1885.

## THE CONSTRICTOR URETHRE MUSCLE: ITS RELATION TO URETHRAL PATHOLOGY AND TREATMENT.

DR. GEORGE H. TILDEN said that Dr. Cabot had not overstated the importance of the constrictor urethre muscle, an importance which in general is not sufficiently appreciated. One of the most striking methods of demonstrating the existence and influence of this muscle is to pass an instrument upon the cadaver, after post-mortem rigidity has set in, when it will be found impossible, without exerting considerable force, either to pass the instrument into the bladder from the meatus or in the reverse direction from the bladder outward; the reason of this being the resistance offered to the passage of the instrument by the post-mortem rigidity of this constrictor muscle, the membranous urethra being thereby closed. Of course after this resistance has been once overcome the instrument passes readily back and forth. The action also of this muscle during life enables us to tell in which of the three divisions of the urinary tract the end of a catheter may be, and to apply injection to any one of the three. When a soft catheter is introduced into the urethra, and fluid injected through the instrument, if the fluid returns at the side of the catheter and comes out of the meatus, we know that the end of the catheter is somewhere in the anterior urethra, on the distal side of the constrictor muscle. If the fluid which is injected does not return at all, either at the side of the catheter or through it, we know that the end of the instrument is somewhere in the posterior urethra, between the constrictor muscle and the internal vesical sphincter; and if the fluid injected returns not by the side of the catheter, but through it, it shows that the eye of the instrument has passed the internal vesical sphincter and is in the bladder. The action of the constrictor muscle influences the diagnosis of urethral disease as well as its pathology and treatment, and it is of the highest importance in any case to determine which region of the urethra is affected, for the secret of the treatment of gleet is to know exactly what you want to do and then to do it. As Dr. Cabot has said, the tonic contraction of the constrictor urethre muscle causes the retention of any purulent secretion which takes place behind it, and this is discharged only during micturition. When the patient is directed to urinate into two glasses and the urine in the first glass is cloudy and contains pus, while that in the second glass is perfectly clear and free from pus, it only shows that there is no inflammation of the bladder, but does not indicate which portion of the urethra is affected. The converse of the above does not hold good, namely, if the urine in both glasses contains pus, it does not follow that the bladder is affected, for the reason that purulent secretions from the posterior urethra may work back through the internal and involuntary sphincter into the bladder, there to mix with the urine, to be eliminated with it during micturition, and thus be present in the urine passed into each glass. The best way of determining whether there is any inflammatory affection of the posterior urethra, by examination of the urine, is to pass a soft-rubber catheter into the bulbous urethra as far as the constrictor muscle, and thoroughly wash out the anterior urethra in its

whole extent, until it is perfectly clean. Any discharge from the anterior urethra is thus eliminated from consideration, and if the patient immediately urinate in two glasses and the urine in the first glass contains pus, while that in the second glass is clear, it is positive evidence that there is inflammation of the posterior urethra somewhere between the two sphincter muscles. Other evidence, of course, is to be derived from the subjective sensations of the patient, frequency of micturition, etc., which, however, are often entirely wanting; from microscopical examination of the urinary sediment, and by examination of the urethra as to sensitive regions and thickenings of the mucous membrane, by means of instruments. The best treatment for the thickened and inflamed patches of urethral mucous membrane, which are so commonly the cause of gleet, is the passage of large-sized sounds, that is, not merely large enough to pass the meatus, which must often be enlarged, but large enough to fully distend the urethra to its individual and normal calibre; and also the application of an aqueous solution of nitrate of silver. In giving injections or making applications to the urethral mucous membrane, it is not a good plan to use fat or vaseline in order to lubricate the instruments employed, as these substances furnish mechanical protection to the mucous membrane and interfere with the full action of the solution used, but glycerin should be employed for this purpose. Cases of gleet sometimes resist treatment with surprising tenacity, and in such cases it is not irrational to suppose that an implication of some of the follicles of the urethral mucous membrane, by the inflammatory process, has taken place. One occasionally sees, during the course of gleet, the development of a very small sinus, not large enough to receive even a bristle, and which opens very near the meatus, within a sixteenth of an inch of it. Such a sinus keeps continually discharging minute quantities of pus, is extremely difficult to close, and is probably caused by the extension of inflammation into one of the mucous follicles just within the meatus. The process forms by extension an opening outside the meatus on the glans penis, thus constituting a fistula of minute size. There is no reason why a similar process should not take place deeper down in the urethra and thus indefinitely perpetuate a slight gleet discharge. This idea receives confirmation from the fact that one sometimes meets with a peri-urethral abscess during gleet, the starting-point of which can hardly be anything but follicular inflammation.

DR. F. B. GREENOUGH said that he had been much interested in the paper, and would only say that he would like to confirm Dr. Tilden's statement that some cases of gleet are very obstinate.

DR. ARNER POST said that he was glad to see so much importance attached to the constrictor urethre muscle, as it is a point usually neglected. The common division of the urethra into prostatic, membranous, and spongy portions is not entirely satisfactory when considering disease of the part; and knowledge of the existence of this external sphincter clears up cases not otherwise explainable, such as the sudden extension of disease to the neck of the bladder after the passage of sounds. At the present day the bladder is often washed out with

a syringe after the method of Dr. Bigelow, and the ease with which it is done suggests that the constrictor may be forced by even a gonorrhoea syringe, provided it is a little too large or is too energetically used. In this way Dr. Post explains cases of sudden inflammation of the posterior urethra, occurring so early that ordinary extension of the disease would not have taken place, even if there were no constrictor.

The speaker also showed a plate from Guion representing the urethra of a seven years' gleet, split open so as to show its abrupt limit at the constrictor and its gradual shading off toward the meatus.

DR. CABOT remarked that in Dr. Bigelow's use of the syringe the patient is etherized. He did not remember seeing it used otherwise, and under ordinary circumstances the constrictor is probably less easily forced than during etherization.

DR. GREENOUGH said that, with regard to urethral injections, he believed there were few methods of treatment in the practice of medicine that had done so much harm as they had, when improperly used. He thought the risk of forcing an injection beyond the constrictor could be avoided, without any pressure in the perinaeum, by regulating the amount of injection to be taken according to the capacity of the urethra in each case, and instructing the patient to press the piston of the syringe down slowly and without force, and to stop as soon as there was any approach to a feeling of overdistention, of which the patient's feeling was the best guide. Of course the capacities of urethras vary, but he thought that, in the earlier stages of gonorrhoea, about two thirds of the smaller size of the Royal Excelsior P. would distend the anterior part sufficiently. He thought that the patient's sensation of distention, with the always advised precaution of washing out the urethra by passing water just before injecting, would prevent any possibility of carrying the injection through the constrictor to the deeper urethra.

## NEW ENGLAND OPHTHALMOLOGICAL SOCIETY.

REPORTED BY MYLES STANDISH, M.D., SECRETARY.

THE President, DR. DEERY, in the chair.

DR. DEERY reported a case of zonular cataract, which became complete after an iridectomy, accompanied by great hæmorrhage.

The case has been already reported in this Journal.

In the discussion which followed, DR. WADSWORTH said that in the first case in which he attempted trituration of the lens it had no effect. Since the first case trituration had invariably effected the result desired. One diabetic cataract was three times pricked through the capsule without effect, but after Förster's operation it became in three months opaque.

DR. SERRAGE inquired of the reader in regard to the amount of pressure exerted in the anterior chamber by the blood.

DR. DEERY replied that the anterior chamber was quickly emptied after the hæmorrhage occurred.

DR. HUNT showed a case of iritis without a rheumatic or syphilitic history. First seen with complete adhesion of the pupillary border to the lens.

The adhesions were broken away, and an extraction done. The eye is to-day perfectly clear (two or three weeks after the operation). Patient now has a cataract forming in the other eye. V. to-day =  $\frac{10}{100}$ . In reply to a question of Dr. Shaw, the reader said that the lens was perfectly opaque when the operation was done.

DR. WADSWORTH reported a case of

### LEAD-POISONING COMPLICATED WITH PROBABLE TYPHOID FEVER.

in which there was double optic neuritis, with paralysis of some of the ocular muscles, which were the only symptoms of the lead-poisoning.

DR. DEERY inquired if there had been any improvement in the vision.

DR. WADSWORTH was not certain, but thought not.

DR. CAPRON inquired if any other member of the family had suffered from lead-poisoning.

The reporter said that there was no other case, unless it was that of a servant, who thought he had experienced a relapse of the pains of lead colic since he came to work at the house of patient. He had suffered from lead colic previously.

DR. WADSWORTH said that in the so-called nuclear disease the muscles were affected in just this way.

DR. DEERY said the prognosis in such cases was very bad, with a possibility of quantitative vision.

DR. HAY reported a case of a man, fifty years of age; said his disease was of three months' duration when first seen. Upon ophthalmoscopic examination, a separation was found on the nasal side, which seemed stationary. V. without glass  $\frac{10}{60}$ . Patient said objects looked greenish. T. not increased. Patient was seen at intervals for five months, with failing vision, until it became less than  $\frac{2}{200}$ . Enucleation was advised.

Two months later the patient came complaining of pain. The T. was increased, and a diagnosis of intraocular tumor was made. The eye was enucleated, and a tumor occupying nearly one third of the globe was found.

DR. STANDISH showed sections of the tumor, which proved to be a round-celled sarcoma springing from the choroid.

DR. MILLER said he had seen an eye enucleated, in which was found only a separation of the retina and choroid. There was slight or no increase of T. The tumor appeared ophthalmoscopically of a brownish color, with the outline well defined and distinct. The tumor increased in size while under observation.

DR. HAY said the difficulty lay in a differential diagnosis between choroidal separation and a choroidal tumor.

DR. CAPRON reported a

### CASE OF DIPLOPIA.

Patient first noticed double vision for distant objects, which gradually transferred itself to near objects. Patient was anæmic and nervous. V. o. d. =  $\frac{20}{20}$  + V. o. s.  $\frac{20}{20}$ . Motion perfect. Images homonymous, and the same distance apart in all portions of the field. Prisms 10° x 8° bases inverted overcame the diplopia. No ophthalmoscopic signs. R. Potass. Iodid. Two weeks later diplopia had en-

tirely disappeared, with the exception of one relapse of twenty-four hours. Patient has had sick-headaches, but no disease discovered. A question of hysteria. To-day patient has congestion of the disks, not previously noticed. V. o. d. =  $\frac{20}{40}$ . V. o. s. =  $\frac{30}{30}$ . In reply to a question by Dr. Dyer, the reader said the images were always on the same level, and in reply to Dr. Sprague said patient had not complained of diplopia with the headaches.

Dr. WADSWORTH agreed with the reader that hysteria was the probable cause.

Dr. HUNT suggested that diplopias were sometimes due to astigmatism, and could be corrected by glasses.

Dr. COGGIN reported a case he had first seen October 18th. Woman, sixty-eight years of age. V. o. d. =  $\frac{40}{40}$ . V. o. s. =  $\frac{30}{30}$  without glass; with. +1.50 D. V. o. u. =  $\frac{40}{40}$ . T. = +1. Pupils and fundus normal. Some opacities of right eye. Dropped in sulphate of atropine, 1 to 1,000 parts, for examination.

October 21st was called to see the patient. Twelve hours after the use of the atropine patient had experienced severe pain in the right eye, with nausea, which lasted thirty-six hours. Vision was lost on the 19th.

When seen, patient had quantitative vision, with dilated pupil and shallow anterior chamber. T. increased, but no pain. R. Eserine.

October 24th. V. o. s., with +1.50 =  $\frac{40}{40}$ . Counts fingers O. D. T. = 1, same as right eye, with small pupil and shallow anterior chamber.

Dr. HAY said he had had a case of glaucoma following atropine.

Dr. ST. JOHN reported the case of a patient who had experienced an attack of simple acute glaucoma. Iridectomy was done, without improvement to vision, however, and patient had used eserine from time to time in the eye.

Patient returned with slight haziness in lens of other eye. T. absolutely normal. Atropine was used once, 1 to 500 parts, and was followed in two hours by great pain.

Next morning T. = 2, with acute glaucoma. Eserine was used, and in two hours the pain was gone, and now vision is back where it was before, although lost meanwhile. The reporter thought the history might indicate some danger in the removal of the lens.

Dr. WADSWORTH said he was sceptical as to the action of atropine in producing glaucoma, and thought that the mental effect of the examination superinduced the disease in a previous glaucomatous condition. He said he had seen a case of glaucoma checked by the use of atropine, giving relief to the pain and congestion. The case had a few posterior synechie, however. There was present a typical depression of the nerve, with pulsating arteries and increase of T.

A new use for Croton oil has been discovered in New Jersey, where a wife sprinkled her husband's underclothing with it to keep him from going out evenings. Her success led her to share her secret with her female friends and an epidemic of erythema among the male portion of the community revealed the agency of the anti-club-persuading medicament.

## PATHOLOGICAL SOCIETY OF PHILADELPHIA.

THURSDAY evening, February 26, 1885. The President, DR. SHAKESPEARE, in the chair.

### SYNOSTOSIS OF THE VERTEBRAL COLUMN.

Presented by A. SYDNEY ROBERTS, M.D.

This specimen of synostosis or calcareous fusion of the dorsal and lumbar vertebrae was removed from the body of an aged man that had been sent from the almshouse to the dissecting-room of the University of Pennsylvania. The pathological character of the specimen will alone be of interest, as all facts pertaining to a personal or clinical history of the individual were unobtainable.

The vertebrae, before my attention was directed to them, had been macerated and boiled, destroying thereby all evidence of the nature of the inflammatory process that caused such extensive synostosis.

In referring to the specimen it will be noticed that the vertebral column is held in a rigid position by a deposit of calcareous plastic material, that extends from the fifth dorsal to the sacrum. In the dorsal region, to the right of the anterior common ligament, a broad ribbon-like band of the deposit crosses the bodies of the lower seven vertebrae. The same fusion exists to the left of the median line between the seventh and ninth dorsal. It is here interrupted by an intervertebral interspace, to again appear between the eleventh and twelfth dorsal and in first and second lumbar. The smooth, plastic character of the effusion is materially altered in the lumbar region, especially noticeable between.

The articulating facets of the vertebrae, with but few exceptions, show evidences of chalky deposit; these margins are nodular and "frilled," between the bodies of the first, second, and third. It is here thickened and nodular, with occasional bony stalactites, markedly contrasting with the smooth, ribbon-like band of the mid-dorsal.

The vertebral lamina frequently coalesce; especially noticeable between the fourth and fifth lumbar and in the lower dorsal regions. The cretaceous deposit occurred in the structure of the intrinsic ligaments of the spine, or those short firm bands that bind the approximating surfaces of the vertebrae together. Between the fourth and fifth lumbar and the attachment of the latter to the sacrum, the ligamentous structures are all involved by the deposit firmly cementing the superincumbent column to the sacrum.

In the tenth, eleventh and twelfth dorsal the articulating facets are obliterated by ankylosis. The same fusion exists between the facets of all the lumbar vertebrae. The extremities of the lower dorsal spinous processes and the last two lumbar are united by ossification of the supra-spinous ligament.

Corresponding with this anomalous condition of the vertebral column and its articulating facets, a similar process may be noted to have occurred at the sacro-iliac juncture; the margins of the articulating plane are here encrusted by calcareous nodules. About the margins of the articulating surfaces for the heads and tubercles of the ribs, the same encrusting chalky concretions have been deposited.

With a view to determining the nature of these plastic effusions, and in lieu of the evidence that would have established the aetiology of the affection, had a careful autopsy been held, I examined portions of the deposits with the nitric-acid and ammonia test with the hope of detecting the presence of uric acid. The results were negative. A crystalline structure could not be detected by microscopical examination; the mass appeared amorphous, yielding bubbles by the addition of acetic acid. It was no doubt largely composed of the carbonate and other salts of lime.

I think it may be inferred that the individual from whom these vertebrae were removed had been afflicted with chronic rheumatic arthritis, as the specimen at least shows the characteristic deposits of the disease.

#### SPONDYLITIS OF THE DORSAL VERTEBRÆ, WITH MILIARY TUBERCULOSIS OF THE LUNGS.

Presented by ALFRED ROBERTS, M.D., for DR. WM. L. PORTER.

Frederick H., a gunsmith, aged twenty-three, a native of Berne, Switzerland, was admitted into the surgical wards of the Philadelphia Hospital under the care of my colleague, Dr. Porter, on January 9, 1885.

He complained of general malaise, great prostration after slightest exertion, and a sharp paroxysmal pain over region of sternum and about the right shoulder-blade. Had always enjoyed excellent health. His parents are healthy and living. Was a moderate drinker, and never had any venereal taint.

During the latter part of August, 1884, five months before admission to the hospital, he commenced losing flesh without apparent cause. The symptom of pain soon followed, located over the ensiform appendix, and a month later he was incapacitated from work by extreme weakness. Upon date of entry a marked angular hump was noticed in the mid-dorsal region of the spine. Pain was now constant in anterior portion of chest, and greatly exaggerated by motion. Vertebral column was rigid; normal curves obliterated by spasm of local spinal muscles.

One week after admission an elastic swelling appeared below the inferior angle of the right scapula; rapidly losing its circumscribed character it spread in all directions. A month later it covered the entire posterior half of the trunk from the spine of the scapula to the belly of the quadratus lumborum, its anterior margin being defined by a perpendicular line corresponding to the pectoral fold of the axilla.

I first saw the patient February 13th (one week prior to his death); he had a rapid, small pulse, shallow respiration, dry, parched skin, and a temperature of 101° F. The abscess had so covered the hump that it could only be detected by deep pressure. He grew rapidly weaker. Morning temperature ranged between 99° and 100° F., with an evening rise to 100°, 101°, and 102°; it did not vary from this range until two days before death. It then fell to normal (98°), and remained there. He died on February 20, 1885.

DR. SHAKESPEARE presented the following report of the postmortem:—

*Autopsy.*—A large fluctuating abscess was noticed externally, covering the posterior portion of the trunk, extending along the spinal column from the third cervical vertebrae to the first lumbar. Skin covering area of distention discolored and wrinkled. Upon cutting into sack of abscess about one gallon of greenish, stinking, semi-purulent fluid escaped. Dorsal muscles near region of hump dissected away from the vertebrae by the burrowing of pus and in the main destroyed. The scapula had likewise been separated from the trunk by the sack of abscess pushing under its inferior angle.

Distention of tissue marked on right side of column. The spinous processes of the dorsal vertebrae were freely movable at apex of hump in all directions.

*Thorax.* From within showed firm pleuritic adhesions in each cavity, more extensive on right side. Lobes firmly bound together. One or two small normal areas at apex of upper lobes. Lung tissue mainly crepitant throughout. Cut surface exhibits cavities in upper lobe. The balance of lung tissue of each lobe studded with gray tubercles. Left lung is in a similar condition, with extensive congestion. Bronchial glands not enlarged.

*Heart and pericardium.* Normal.

*Liver.* Small; color, red; appearance of cut surface, normal. Numerous diaphragmatic adhesions. Capsule thickened irregularly. Gall-bladder, normal.

*Spleen.* Flabby; numerous adhesions to diaphragm, with evidence of peritonitis; dark maroon

in color, slightly matted. Pulp, soft. Size, normal. Kidneys: Slightly enlarged. Capsule readily stripped, leaving a pinkish-gray surface, with some injection of vessels between the "pyramids of Ferriin." Cut surface shows cortex thicker than normal, medullary portion pink in color.

Vertebral column. The sack of the abscess in the thorax occupied the region of the media sternum. It covered the bodies of all the vertebrae from the second to tenth dorsal. The anterior common ligament was destroyed and their surfaces were eroded; caries had eaten away the greater portion of the bodies of the seventh and eighth dorsal. The heads of the ribs articulating upon these vertebrae were loose in the sack of the abscess.

#### ESSEX SOUTH DISTRICT MEDICAL SOCIETY.

C. C. SHELTON, M.D., SECRETARY.

A STATED meeting of this Society was held at the Essex House, Salem, on Tuesday, January 27th. Dr. C. C. PIKE, of Peabody, presided.

After the usual supper, a paper was read by Dr. C. W. GALLOPPE, of Lynn, on

#### THE RESULTS OF LISTERISM IN AMPUTATION OF THE BREAST.

This consisted in an analysis of the cases of excision of the breast performed at the Massachusetts General Hospital since February 7, 1877, when Dr. H. J. Bigelow first performed the operation, using all the details of Listerism. Of the 111 cases so treated, 80 were of cancer of the breast, and to the consideration of these the paper was particularly addressed. Tables and remarks were given, stress being laid on the points of age, social condition, side affected, and duration of the disease. The manner of the operation was described, and the variety of dressing mentioned of each case, whether full, partial, or modified Listerism was employed.

As the result of the analysis, and a comparison with modes of after treatment usually employed, the following conclusions were drawn:—

(1) Antiseptic treatment has reduced the death-rate from 11 per cent. to 8 per cent.

(2) It has reduced the amount of crabs from 11 per cent. of all cases operated on to 1 per cent. This is a remarkable advance in surgery, and is still more noteworthy when we consider that 7.1 per cent. of the cases under open dressings were fatal, while under Listerism the attacks were uniformly light.

(3) Listerism has not affected the death-rate from septicaemia and pyæmia, being 1 per cent. under all dressings.

(4) It has practically introduced a new danger, that of carbolic-acid poisoning: 12 per cent. of the cases were thus affected, and two cases may have owed their death to this cause.

(5) It has reduced the average stay in the hospital from forty-two to thirty days, thus allowing 10 per cent. more cases to be treated with the same accommodations.

(6) It has to a slight extent reduced the severity of the medical fever.

In addition to these benefits it has made a saving to the hospital in time and money; it has lightened the labor of attendants by doing away with frequent dressings; and, finally, by collecting and disinfecting the discharges from wounds it has made the atmosphere more pure, and less liable to be the vehicle for diffusing the germs of septic disease.

Dr. PIKE called upon Dr. A. T. Cabot, of Boston (who, with Dr. George B. Shattuck, was present as the guest of the Society), to open the discussion.

After expressing his pleasure in being present, and his interest in the subject of the paper, Dr. CABOT said that the hospital cases represented various degrees of completeness as regarded antiseptic dressings, and when it was remembered that house officers and nurses were frequently changed, and that each new one had to familiarize himself by experience with the detailed process, it must frequently happen that wounds would not be rendered perfectly aseptic, and a high death-rate would not be unexpected.

On the Continent, the details of Listerism were constantly being modified, the tendency there being to the use of dry, absorbent dressings, such as wool-wool, dry gauze, absorbent cotton, etc., the results thus far having been favorable; the presence of moisture, of course, favoring putrefaction.

Dr. Cabot dwelt on the importance of thorough drainage, but said that drainage-tubes were of use chiefly in removing the serous discharge of the first twenty-four hours, and if left too long became themselves irritating, and were likely to lead to the formation of troublesome sinuses.

On account of the danger of carbolic-acid poisoning various substitutes for this acid were used, such as thymol, phenyle, and solutions of corrosive sublimate. The objection to the last was the fact that the discharges from a wound formed an albuminate of mercury, which was not so strong an antiseptic. The speaker had himself been quite in the habit of using chlorinated soda of the strength of 1 to 10 or 15.

Dr. GEORGE Z. GOODELL, of Salem, then read a paper on

#### A CASE OF IODOFORM-POISONING.

Mrs. R., about forty years old (married to her second husband), of irregular habits, whose mother and one brother died of consumption, and her other brothers and sisters, three in number, died while quite young, gives a history of ragged and indolent ulcers in various parts of the body for seven years previous to the case we have under consideration, all of which have left white, glistening scars.

In August, 1881, a swelling appeared under the chin and a little to the left of the median line. This was poulticed, and, breaking down, discharged a little pus, and then, the skin sloughing, left a ragged ulcer over an inch in diameter. At the same time she began to have soreness in the throat and hoarseness.

I was first applied to on September 21st, and prescribed specific treatment, with zinc ointment to the ulcer. This treatment had no effect in reducing the size of the ulcer, and on March 20, 1882, I ordered

## Medical and Surgical Journal.

THURSDAY, APRIL 9, 1885.

fifteen grains of iodoform in one ounce of petroleum ointment, to be applied twice daily on lint to the ulcer, and discontinued the zinc ointment.

On March 29th, having used the salve for nine days, her face was red and swollen, and I applied cloths wrung out in cold water.

March 30th. The face was more swollen, and covered by a large number of small vesicles discharging yellow serum, and giving the room a strong odor of iodoform. The patient complained of an intense smarting, burning, and tightness of the skin, without headache, and also of tasting the salve. I changed the cold water to alcohol and water, equal parts, which gave considerable relief, and stopped the ointment, a case reported by Dr. W. C. B. Fildes<sup>1</sup> being fresh in my mind.

March 31st. The temperature was 102° F., and the next day, she being slightly delirious, with weak and irregular pulse, Dr. Carlton saw the patient with me and advised quinine. She improved; and April 4th the temperature was normal, hands and face were both drying up, and from this time she had uninterrupted recovery, the skin of the face and hands peeling off in large flakes, leaving clear skin about April 17th. The ulcer healed entirely during these three weeks, and has only troubled her since for a week or so at a time.

Dr. SHATTUCK, of Boston, was invited to open the discussion. He remarked that the case reported showed a certain idiosyncrasy on the part of the patient, and dwelt on the caution which such experiences should teach the practising physician.

Dr. CABOT spoke of a child in whom a carious cavity of the ulna was packed with iodoform on charpie, who showed symptoms of stupor, vomiting, and diarrhoea, these symptoms disappearing after the omission of the iodoform.

Dr. COLMAN had seen symptoms of poisoning following the introduction of an intra-uterine pencil of iodoform of the strength of one grain.

Dr. CABOT remarked that in some fatal cases reported abroad the unfavorable symptoms had not been relieved by the omission of the iodoform, and that it was less freely used than formerly on the Continent.

Dr. T. L. PERKINS showed the right parietal bone of a child's skull, showing cephalæmatoma, with effusion external and internal. The tumor appeared the second day after birth, increased rapidly, with symptoms of compression, and death. There was a bloody fluid, which did not coagulate after removal.

Dr. A. H. JONSSON made extended remarks on the case and the subject.

Dr. PIKE asked the opinion of the surgeons present with regard to a man under his care. The man was working every day, and shows no constitutional symptoms whatever, but has a fluctuating tumor over region of left kidney. The aspirator detects pus. Drs. Arthur Kemble and Cabot both advised aspiration.

Dr. JONSSON, of Salem, reported a case of confinement in which the placenta was edematous and friable, a large piece being retained, and expelled after the use of ice and ergot. The child was still born, and its abdomen contained a pint of ascitic fluid.

## WOLFF'S TREATMENT OF "WRITER'S CRAMP."

AMONG the therapeutic advances with which, during the past few years, the art of healing has been enriched, that one to which the above heading refers richly deserves to be singled out for special consideration.

Of course, the fact of central importance is that — if well-authenticated evidence is to be believed — a way has been found of dealing successfully with a distressing and intractable malady. But, besides this, a certain picturesque interest attaches to the fact that it was reserved for a layman to discover and present to us the key which professionals had sought in vain. We say "discover," because although massage and exercises have often enough been used in these cases, no one hitherto has pretended to offer a method of treatment anything like so complete or anything like so successful. In fact, Mr. Wolff's method is so peculiarly his own that although it has been for several years before the public he seems to have found but few successful imitators in its use.

The clinical features of the large group of affections of which writer's cramp, or palsy, is the most prominent member are well known to all. Overuse of certain muscles — often on a basis of imperfect natural vigor, which makes very moderate use count as overuse — induces localized disorder of function, betrayed by weakness or spasm, or both, and in many cases severe pain, which often extends to other parts of the limb, and may eventually constitute an independent and almost ever-present symptom.

The unhappy sufferer usually tries "rest," by his doctor's advice, and at the end of a year's vacation finds himself, as an almost invariable rule, no whit better off than he was at the beginning.

Galvanization and massage (in the ordinary sense) may bring him partial, or — if he is very fortunate, and the case be not a bad one — even complete, relief, but the chances are strongly against

<sup>1</sup>Journal, March 16, 1882.

this result. We have known one gentleman who cured himself by persistent exercise at the gymnasium, where he diligently used the large hand-roller, and this fact is of special interest. But such results are exceptional, and as a rule the sufferer, after finding that the spasmodic force with which his fingers grasp the pen does not avail to keep it in their control, resorts to mechanical contrivances which shut out the fine muscles of the hand, and make those of the arm and shoulder do duty instead. The electrical irritability of the small muscles of the hand is almost always altered, to delicate tests, and this has very properly been adduced to sustain the view that local changes of nutrition in the muscles and nerve filaments constitute the essential pathology of the disease. Whether the central nervous system is conjointly implicated or not is problematical, but in some cases at least it may be, possibly primarily but more probably secondarily, involved to some degree.

Mr. Wolff was, we learn, a teacher of penmanship at Frankfort-on-the-Main, and was led to interest himself in this subject by a desire to improve the cramped and awkward writing of some of his pupils. Beginning in this way, and studying the muscular mechanism of the hand, he gradually extended his investigations to true "writer's cramp," and for the past few years has been treating successfully cases of this kind for a number of eminent physicians in Germany, France, and England. The latest endorsement comes from Dr. DeWatteville, of St. Mary's Hospital, London,<sup>1</sup> who gives the histories and facsimiles of the handwriting, before and after treatment, of several interesting cases.

Mr. Wolff's method consists — so far as a verbal account can make it clear — in a mixture of massage, of vigorous stretching of the muscles liable to spasm, and of prolonged active and passive exercises, a portion of which are done under the coöperation of the operator, others by the patient alone, or with the aid of elastic bands, which are attached to the arm and fingers in various ways. During the brief time over which the treatment extends (only four or five weeks in all) the patient is expected to give up several hours daily to these exercises, and must live temporarily for his muscles alone. This seems to be a condition *sine quâ non* of success.

It is said to become evident after a few days of treatment whether a given case is likely to respond to the method, but it is by no means the cases which at the outset seem the worst that are discarded.

After a short time of this vigorous manipulation, etc., the patient is made to take up his pen, not as a test of the cure, but as a part of the treatment, and carefully graded exercises are gone through, covering soon, in some cases, several hours daily. The disease is, in short, attacked in open field,

and exercise of the affected muscles, which was the cause of the mischief, is converted into a means of restoring health.

Much is made of the *stretching* to which certain of the muscles are subjected, and, whether rightly or wrongly, the mind reverts to the nerve-stretching which has been so much employed for the relief of pain and spasm, and which probably acts largely by temporarily diminishing the conductivity, and by altering the conditions of nutrition of the diseased nerve fibres. By these various means, large numbers, and in fact a large per cent. of severe cases, have been rapidly and, as it would seem, permanently cured, so that the patients could take up again their professional employments.

These facts convey another lesson: namely, that if cures are possible, *prevention* ought to be still more easy, and that professional writers ought to be taught, on the first hint of fatigue, systematically to strengthen the muscles from which they demand so much.

We can bear witness, from personal experience, that the use of Wolff's treatment, even in unpractised hands, is capable of developing the strength and volume of such affected muscles, but, alas, also to the fact that this result alone does not necessarily bring about a cure of the spasmodic and paralytic symptoms of writer's cramp.

#### CURE OF ANEURISM OF THE ABDOMINAL AORTA BY LAPAROTOMY AND INTRODUCTION OF SILVER WIRE.

The attempt to cure an aneurism by coagulation of the blood through the introduction of foreign bodies into the sac has been tried on several occasions. Moore, in 1864, used iron wire; Levis, in 1873, horsehair, of which he introduced about twenty-five feet into an aneurismal sac; Bacelli, fine watch-springs; Schrötter, in a case lately reported, introduced into an aneurism of the thoracic aorta 126 cm. of Florence silk through a canula in divided portions at two insertions. This patient died fifteen days after the second operation of pulmonary oedema, and the autopsy showed that the sac of the aneurism, which protruded from the wall of the chest, was entirely filled with coagulated blood.

The peculiarity of the case now reported by Loreta, of Bologna, consists, not only in the eminently successful result, thereby differing from previous attempts, but in the fact that the aneurism affected the abdominal aorta and necessitated a laparotomy.

Details of this case and of the operation are given in the *Deutsche Medizinische Zeitung* of March 23, 1885. The patient, a sailor, aged thirty, had suffered for two years. While hoisting sail he suddenly felt sharp pain in the epigastrium. Later he noticed a pulsation in the same spot and, in addi-

<sup>1</sup> British Medical Journal, February 14, 1885.

tion, pain developed in the region of the stomach, accompanied by disturbance of digestion, and numbness with pain in the lower extremities. The difficulty increased so much in the course of a year that the patient sought relief in the surgical clinic of Bologna. The examination showed the following facts: The man was pale and emaciated. In the epigastrium was noticed a pulsating tumor of the size of the head of a nine months' fetus. Auscultation revealed a prolonged blowing murmur loudest in the left half of the abdomen. On these and other grounds the diagnosis was made of a sacculated traumatic aneurism of the aorta. In view of the discomfort, pain, and extreme emaciation, death was to be expected unless prompt relief could be given. Therefore Professor Loreta concluded to perform laparotomy with the object of separating the aneurismal sack from the blood current. The operation was performed on December 18, 1884. An incision was made from the ensiform process to the umbilicus. Strong and extensive adhesions between the peritoneum omentum and stomach were separated, the mesocolon was cut through, and the organs drawn aside till the tumor was exposed. The walls of the aneurism were so thin that it was feared that a ligature applied below the sack might produce rupture; the operator therefore concluded to introduce a wire into the sack to produce coagulation of the blood. With a slender trocar he made a puncture and carried through the canula as much fine silvered copper wire as the space in the sack allowed: in all, two meters. The outer end of the wire was also pushed in.

The opening was touched with a concentrated solution of carbolic acid in order to shrink the tissues, the abdominal organs were brought back to their original position, and the wound sewed. The operation lasted an hour and a quarter. The same evening the patient no longer complained of the pains previously felt, and was able to sleep quietly, which had not been the case for weeks.

On the twenty-seventh of December, the ninth day after the operation, the first change of dressing was made; the wound was healed by first intention. The pulsation of the tumor was hardly perceptible, the murmur was very weak, the sack markedly diminished; the femoral arteries, which before the operation had shown only a weak pulsation, now pulsated very perceptibly. Twenty days after the operation no trace either of pulsation or of murmur was to be found, and the sack was about the size of a nut. The patient is now completely restored and can resume his occupation.

Professor Loreta looks upon the use of the wire as the cardinal point of his success. This, at first, produced a coagulation, and later, on account of its thinness and pliability, opposed no obstacle to the shrinking of the clot. Although in only one of the cases above cited was death, which followed,

supposed to be in any way attendant upon the interference, they tend to emphasize the uncertainty of the operation as well as the good fortune of Professor Loreta. It is very possible that these operations were too long delayed, however, and that an earlier resort to the procedure will prove more successful.

#### SEVENTY-FIRST ANNUAL REPORT OF THE MASSACHUSETTS GENERAL HOSPITAL AND THE McLEAN ASYLUM.

THE trustees of this fine old institution acknowledge the receipt during the year, in donations and legacies, of \$84,475, which indicates that the Massachusetts General Hospital has not lost its claim upon the benevolent instincts and purposes cherished by the people of the State. The chief outlay, other than usual expenses, has been in the direction of repairs, which have necessitated an expenditure of \$18,593, which is \$11,000 more than the average for the past five years. The most expensive items were a complete reorganization of the sewerage of the hospital, which for some years has been a source of anxiety and danger; repainting; and the substitution of brick piers for piles under wards A and B.

The system of sewerage, just replaced, had been in existence, with some modifications, since 1821, when the original granite building was constructed. The sewage was then carried to the shore of Charles River, lying within one hundred feet of the main building, by a drain of elliptical section, large enough to admit a man; size at that time and until within comparatively recent years being, as was supposed, in direct proportion to excellence. As the shore-line was gradually carried westerly, the drain was extended in the same direction, and as the drain discharged only at low tide, large cesspools were added. The whole system had the defect of irregular and slow delivery and constant retention. It was designed with the best knowledge of the time, to meet the conditions then existing, but under new conditions and with larger experience, was only to be condemned and replaced. The new intercepting sewer, having been carried through Charles Street, gave an outlet for constant and rapid discharge. A new drain of ten-inch glazed pipe has been laid, and the old drains and cesspools opened, cleansed, and solidly filled, for a distance of thirty feet from the house, with fresh earth mixed with sulphate of iron and chloride of lime, brick cement and concrete cutting off the terminal extremity.

Wards A and B, built in 1873 and designed for temporary structures to be taken down and rebuilt after ten or twelve years' service, have proved so much more durable than was expected and have retained so perfectly their original high sanitary condition that it was thought worth while to repaint

them and substitute, as mentioned, brick piers for the decaying piles. The general good condition of the main house, after the wear and tear of more than sixty years, is reported as proof of the excellence of the original design and construction; but extensive repairs and improvements will be needed within the next year to keep the hospital up to its present efficiency.

The trustees report that the Convalescent Home at Belmont justifies the expectations which were formed of its usefulness. It has not been occupied to its full capacity, and the public are reminded that "it is designed not only for convalescents from our own, but also from other hospitals, private houses, and boarding-houses."

The report of the resident physician, Dr. Whittemore, whom the hospital is fortunate in still having in its service, notwithstanding the personal trials from ill-health which he has had to sustain during the year, shows the same enrious disproportion between medical and surgical patients we have remarked upon before. Of the patients admitted during the year 1,293 were surgical and only 803 medical. The number received on account of accident was 397. Of the 2,096 patients, 382 were paying, 47 were partially paying, 1,667 were entirely free; 1,043 were Americans, 1,053 were foreigners; 1,266 were males, 830 were females. The proportion of deaths to the whole number of results was 9.14 per cent.

The greatest number of paying patients at any one time was 40; in private rooms, 8; the greatest number of free patients, 159; the greatest total, 186. The least number of paying patients at any one time was 14; in private rooms, 1; the least free, 106; the least total, 129. The proportion of ward beds occupied by free patients was 81 per cent.; by paying patients, 16 per cent. About 14.2 of the paying patients occupied private rooms. The average number of patients was 161; males, 97; females, 64.

The average number of paying patients was 28, of whom 20 would be Americans and 8 foreigners. The average number of free patients was 133; Americans, 63; foreigners, 70. The average time of paying patients was 3 weeks; of free patients, 1.14. Of the free patients 16 per cent. were female domestics; 24 per cent. laborers; 16 per cent. mechanics, and 9 per cent. minors.

The new out-patient building has fulfilled all expectations entertained in regard to it; 36,237 out-patients, giving an average attendance daily of 111, have availed themselves of the privileges there offered.

At the McLean Asylum for the Insane, as we learn from the report of Dr. Cowles, the superintendent, there were 113 admissions during the year, the whole number of cases treated was 278, representing 272 individuals, of whom 103 were discharged.

Of the 109 persons admitted, 70 persons were regarded as recent cases, and 39 as chronic, or as incurable.

Seventy-five persons, 40 men and 35 women, had never been in any hospital. Of the remaining 34 persons, 18, 7 men and 11 women, were admitted for the second time; 10, 4 men and 6 women, for the third time; 2, 1 man and 1 woman, for the fourth time; 1 woman for the fifth time; 1 woman for the eighth time; 1 woman three times, being the fourteenth, fifteenth, and sixteenth admissions respectively; and 1 man for the eighteenth time.

Fifty-three cases, representing 49 persons, 25 men and 21 women, were admitted as voluntary patients upon their written applications. Two men and one woman were not insane.

The whole number of persons admitted as voluntary patients under the present law is as follows, namely, 1881, 1; 1882, 11; 1883, 33; 1884, 49. The whole number of persons admitted during the past five years is as follows, namely, 1879, 74; 1880, 51; 1881, 63; 1882, 82; 1883, 107; 1884, 109. In 1884 there were four more admissions, eight less discharges, and two more cases under treatment, than during the year 1883; and the number present was ten more at the end than at the beginning of the year.

The average duration of illness from the beginning of attack of all cases recorded was 10.52 months, and the average duration of their hospital residence was 7.22 months. The percentage of recoveries on admissions was 30.09. There were three less recoveries than in the previous year, and the same number of deaths (17). The small proportion of recoveries of the voluntary cases, eight in fifty-two cases, points to the more serious character of the attacks of mental disturbance—at least one third being of the chronic class when admitted. The voluntary relation on the part of the patients remaining in the asylum, however, is satisfactorily maintained, and the effect of the presence of such cases in the institution is said to be increasingly good in many ways.

The nearly equal results of the last two years' work in relation to the numbers admitted and treated are thought to indicate that the limit of the capacity of the asylum has been reached. In fact, it has been quite full during all the past year; and a larger number than usual of applicants for admission has been turned away.

The proposed training-school for nurses has been established during the past year, and will doubtless prove, what it is intended to be, an advantage both to the hospital and the general public.

SIR HENRY THOMSON has recently written a clever novel with the title of "Charley Kingston's Aunt." It is said to have been very favorably received in England.

## THE ANNA JAKUES HOSPITAL.

NEWBURYPORT has at last a hospital. It was founded by the munificence of Miss Anna Jaques, a wealthy maiden lady, who left thirty thousand dollars for this object. Other sums were subsequently added by benevolent individuals.

The hospital building commands a slightly situation in Broad Street, in the part of the town known as Belleville. It is well furnished with all the appurtenances of a thoroughly equipped modern hospital, and has a staff of attending physicians consisting of Drs. F. A. Howe, G. W. Snow, E. P. Hurd, J. F. Young, George Montgomery, J. J. Healey, and H. F. Adams (members of the Massachusetts Medical Society), each physician having a term of service of about two months in the year. This hospital can well accommodate, at the present time, twenty patients; there are now about one half that number. By the generosity of certain societies and corporations several free beds have been endowed.

Much of the surgery of this little city of 11,000 inhabitants naturally drifts into the Anna Jaques Hospital, and the members of the staff have already been called upon to perform many capital operations. The hospital will be of growing importance to Newburyport and its section of the State, and the city is to be congratulated on its possession.

## MEDICAL NOTES.

—The discovery is announced by Professor Sigmund Exner, in his work, "*Die Innervation des Kehlkopfes*" (Vienna, 1884), of a third laryngeal nerve—*nervus laryngeus medius*. This nerve is derived from the pharyngeal and laryngeal plexus formed by the pharyngeal branch of the vagus with other nerves, and enters the crico-thyroid muscle, which is also supplied by the external branch of the superior laryngeal nerve. The interarytenoid muscle is supplied by both upper and both lower laryngeal nerves, and, generally, each muscle is innervated by several nerves. The above conclusions are deduced from three lines of research: (1) irritation of nerves in living animals; (2) degenerations of nerves after section in living animals; (3) examination of the larynx in children (*post-mortem*).

—Dr. Watelet, the physician in attendance upon Bastien-Lepage, the French painter lately deceased, has been fined 100 francs for having violated the rules of professional secrecy in writing a short note for the public press. The note was intended to set at rest some slanderous stories that had been circulated concerning the nature of Lepage's disease, and simply stated that the patient died of a cancer. Although it was admitted that this was done only out of kindness to the memory of the deceased, it nevertheless constituted a breach of the penal code.

In this country the law against the publication of professional information in the daily press is somewhat less stringent.

—In the *Lancet*, January, 1885, Surgeon-Major Alexander narrates the following case bearing on some recent remarks made concerning the convict, Mrs. Gibbons. In 1875 the author was sent for hurriedly to see an officer, whom he found lying on a couch with two incised wounds on the front of the abdomen, and one similar wound on the back, near the spine. Twenty-six incised wounds were found about the left breast, both hands were dreadfully mutilated, and lying close to the officer was a sword covered with blood and bent to an angle of forty-five degrees. The patient lived for several hours, and told the author how he had inflicted all these wounds upon himself. Had this gentleman been found dead, it would have been very hard for a jury to give a verdict of suicide.

—EGYPTIAN RAGS DETAINED. — A consignment of five hundred bales of rags shipped from Alexandria, Egypt, to the port of Boston by the agent of a Connecticut paper-mill, has been detained at the Hoosac Tunnel docks in Charlestown by the Boston Board of Health. The bales are all stamped with the seal of an inspector at Alexandria, appointed by the United States Government. The stamp indicates, what an examination of the bales proves, that they have been subjected to the action of sulphurous acid, and the decision must be reached whether these rags are safe or not.

—Dr. H. N. Martin, of the Johns Hopkins University, has replied with vigor to the *Zoophilist*, an anti-vivisection organ of England, in which he was savagely assaulted.

## Correspondence.

## THE SANITARY CONDITION OF NANTUCKET.

Boston, April, 1885.

*Mr. Editor*, — In a recent elaborate article in the *JOURNAL*, over the signature of Harold Williams, M.D., entitled "The Sanitary Condition of Nantucket," the writer devotes himself, almost exclusively, to the task of discrediting the accuracy of the Report of the State Board of Health, Lunacy, and Charity, relative to the same subject.

It is only necessary to turn to the report itself to determine the question as to its accuracy, as compared with Dr. Williams's own statement.

Before taking up some of his remarkable assertions *seriatim*, it should be understood that the statistics quoted in the report were compiled directly from the State Registration Reports, which, so far as mortality is concerned, must depend on the individual certificates of physicians, and are presumably as correct as it is possible to make them.

Dr. Williams's experience at Nantucket, so often quoted in his letter, extending over a fraction only of each year, since the summer of 1881, has to do with a brief period with which the Report of the Board, written in 1883, is but little concerned.

On the other hand, the period referred to in the report embraces the years from 1863 to 1881 (mor-

tality reports); 1871-1881 (reports of specified diseases), during which time there were in practice on the island at least two respected members of the State Society, each of whom practised there at least forty years and must have contributed to the reports referred to.

(1) Dr. Williams states: "The report relies chiefly on its statistics for the conclusions reached." On the other hand, the report carefully avoids such a conclusion, as may be found on pages 194, 198, and 205; it being distinctly stated in the latter place that "the opinion of the Board as to the sanitary condition of Nantucket is *not* formed from statistics alone. . . . Other data were taken into consideration, such as the sanitary condition of the town," etc.

(2) Dr. W. states: "The State Board has compiled its statistics on the number of *burials*." Very true, and the same rule is also applied to every city and town in the State, Nantucket not excepted. In this connection, due notice was given, in the report, of Captain Allen's researches, relative to the burial of bodies brought from other places. Dr. Williams carefully omits any allusion to Captain Allen's admission that the bodies thus brought to Nantucket were of *natives of the island* and the obvious bearing of this fact upon the subject.

(3) The predominance of old people at Nantucket is admitted in the report, and its bearing upon the general question is discussed on page 195. How, then, can the *ill-regulated hand-feeding of infants* be claimed as an exceptional cause of mortality in a population which Dr. W. has just claimed to be made up of *old people*, and where the birth-rate is very much less than the death-rate?<sup>1</sup>

(4) Dr. W. states that the estimates of the Board are based upon an *underestimated* population, while the contrary is the fact, for the period named (mortality statistics 1853 to 1881). For more than three-fourths of this time the population was rapidly diminishing, and not appreciably affected by a summer population, and hence *overestimated* for each year after the census years.

For the other years specified (infectious diseases, 1871-81), the population was also overestimated. Population 1870, 4,123; in 1880, 3,727; or according to Dr. Williams's more favorable estimate (1,000), it was still overestimated.

More accurately the population rapidly diminished from 1870 to 1876 or 1877, and then gradually increased.

(5) We are left to infer from Dr. Williams's reasoning that typhoid fever and diphtheria are almost unknown upon the island, the curious explanation being given that the recording physicians were *unqualified men*, without diploma or medical education. If these empirics, in certifying to certain deaths from obscure diseases, recorded them as typhoid fever, may we not then reasonably inquire, Why should not these same empirics record actual deaths from typhoid fever under the name of other diseases?

(6) If the writer had paid the least regard to the elementary principles of mathematics, he would not have made the gross blunder of misrepresenting the report, as he has taken pains to do in *Italics*, affirming that the "State Board has compared the deaths from phthisis with the total number of deaths, instead of with the total population." Now, this is exactly the reverse of the truth, for the State Board *did* compare the deaths from phthisis with the *population*, as any one may readily see by computing the ratio of 237 (total deaths from phthisis for 11 years at Nantucket) with 3,727 (population), which is precisely 63.59 per 1,000 of the population for the time specified. Hence the illustration which is offered is entirely superfluous.

(7) It is also affirmed that Captain Allen's statistics

of this disease—phthisis—are omitted. On the contrary, they may be found published on page 202, over Captain Allen's signature.

(8) As to the correctness of the quotation from Dr. Bowditch's excellent report. The conclusions in this report are deduced from facts, or statistical data, and from medical opinion. The map from which Dr. Williams appears to have quoted his statement as to the rarity of consumption at Nantucket, was drawn to illustrate *medical opinion only* upon the subject. Dr. Williams has carefully avoided any allusion to the *facts* which Dr. Bowditch publishes on page 71 of the article referred to.

The percentages published in the Report are herewith reproduced.

TABLE 1. SHOWING CONSUMPTION SLIGHTLY MORE PREVALENT IN THE ATLANTIC THAN IN THE INLAND COUNTIES.

Inland Counties, 1849 to 1882.	Percentage of Deaths from consumption to all Deaths.	One Person from consumption in every	Atlantic Counties.	Percentage of Deaths from consumption to all Deaths.	One Person from consumption in every
Berkshire	21.27	67	Barnstable	25.30	60
Franklin	21.17	56	Bristol	23.82	50
Hampden	20.40	35	Dukes and Nantucket	28.99	50
Hampshire	22.18	33	Plymouth	27.73	47
Middlesex	21.21	53	Essex	22.97	48
Norfolk	20.22	58	Suffolk	15.91	42
Worcester	22.39	48			

This certainly does not have the appearance of a *rarity* of the disease, notwithstanding the experience of Dr. Williams. Since the publication of Dr. Bowditch's report the prevalence of the disease appears still more evident, as the following table will show:—

TABLE 2. MORTALITY FROM CONSUMPTION BY COUNTIES FOR TEN YEARS, 1871-1880.

Mean rates per 1,000 of the Population.	Mean rates per 1,000 of the Population.
The State . . . . . 3.26	Nantucket . . . . . 6.46
Dukes and Nantucket . . . . . 4.39	Dukes . . . . . 2.77
Suffolk . . . . . 3.39	
Barnstable . . . . . 3.55	
Essex . . . . . 3.46	
Middlesex . . . . . 3.41	
Bristol . . . . . 3.25	
Plymouth . . . . . 3.19	
Hampshire . . . . . 3.63	
Worcester . . . . . 2.89	
Hampden . . . . . 2.86	
Norfolk . . . . . 2.83	
Franklin . . . . . 2.78	
Berkshire . . . . . 2.26	

I have here separated the two counties, and given the correct figures in the right-hand column to show in what manner the Registration Reports have for many years done an injustice to Dukes County by compelling it to bear an equal burden with Nantucket.

(9) The Board is misrepresented in the statement that it had consigned the inhabitants to *provide* a pure water-supply. Nothing of the sort was written or intended, as the following quotation from their report will show:—

"As a further measure of protection to the public health, the *control of the present watershed* of the public water-supply is a matter of importance, and its use for domestic purposes should be so restricted as to guard the pond from pollution, since a small pond without a natural outlet or inlet, however pure its water may be, becomes proportionately more dangerous under

<sup>1</sup> Births at Nantucket, 10 years, 1870-81, 660. Deaths at Nantucket, 10 years, 1870-81, 1,606.

<sup>2</sup> Page 71, Medical Communications of the Massachusetts Medical Society, vol. x, 1862.

<sup>3</sup> Forty-first Registration Report, page 97.

conditions liable to contaminate, than a larger source with a constant overflow."

The Board were well aware of the purity of the water-supply, but something more was requisite; and that was the guarding of this supply from future pollution.

(10) A careful perusal of the engineer's report will convince the candid reader that the question of sewerage is not so insurmountable as your correspondent states in his letter.

Finally, the Board arrived at its conclusions mainly in consequence of certain conditions mentioned in the

report, and to which the attention of its Committee was directed while at Nantucket, and which had been common sources of complaint, such as the crowded proximity of cesspools, vaults, stables, and wells, the objectionable outlets of sewers opening into a small landlocked basin near the railroad, the collection of putrid and decaying odal upon the wharves, and the defective drainage in different parts of the town.

It is gratifying to learn that an efficient Board of Health has remedied many of the evils which were then in existence.

Very truly yours,

S. W. ABBOTT, M.D.

# REPORTED MORTALITY FOR THE WEEK ENDING MARCH 28, 1885.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from				
				Infectious Diseases.	Lung Diseases.	Diarrhoeal Diseases.	Diphtheria and Croup.	Scarlet Fever.

Deaths reported 2,268; under five years of age 717; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhoeal diseases) 200; lung diseases 456; consumption 231; diphtheria and croup, 100; scarlet fever 35; diarrhoeal diseases 27; measles 28; typhoid fever 21; cerebro-spinal meningitis 13; erysipelas 12; whooping-cough 11; malarial fevers 12; puerperal fever eight. From measles, New York 28, Philadelphia four, St. Louis three, New Bedford two, District of Columbia one. From typhoid fever, Philadelphia nine, New York and Baltimore three each, Boston two, District of Columbia, Providence, New Haven, Nashville, Lawrence, and Lynn one each. From cerebro-spinal meningitis, New York six, Philadelphia, Baltimore, Nashville, Lowell, Fall River, Salem, and Taunton one each. From erysipelas, New York six, Philadelphia four, Boston two. From whooping-cough, New York nine, Philadelphia two. From malarial fevers, New York six, St. Louis three, District of Columbia, New Haven, and Nashville one each. From puerperal fever, New York, Philadelphia, and District of Columbia two each, Baltimore and New Haven one each.

Cases reported in Boston: measles 50, scarlet fever 36, diphtheria —.

In 113 cities and towns of Massachusetts, with an estimated population of 1,416,616 (estimated population of the State 1,555,101), the total death-rate for the week was 19.09 against 19.30 and 19.48 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,906,146, for the week ending March 14th the death-rate was 22.1. Deaths reported 3,779; infants under one year of age 939; acute diseases of the respiratory organs (London) 455, measles 129, whooping-cough 119, diarrhoea 11, fever 31, scarlet fever 31, diphtheria 20, small-pox (London 22, Manchester three, Bradford and Cardiff one each) 27. The death-rates ranged from 13.5 in Birkhead to 18.3 in Sunderland; Birmingham 19.1; Blackburn 22.7; Bradford 23.5; Hull 16.9; Leeds 19.9; Leicester 20.7; Liverpool 25.6; London 21.1; Manchester 28.6; Nottingham 25.2; Sheffield 20.7. In Edinburgh 18.3; Glasgow 20.0; Dublin 29.5.

For the week ending March 11th in the Swiss towns there were 31 deaths from consumption, lung diseases 32, diarrhoeal diseases 11, small-pox (Basle seven) eight, diphtheria and croup four, erysipelas three, measles two, scarlet fever, whooping-cough, and phoid fever one each. The death-rates were: at Geneva 18.2; Zurich 17.5; Basle 25.7; Berne 22.9.

The meteorological record for the week ending March 28th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Date.  March,  1885.	Barom- eter.	Thermometer.			Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE WEEKS ENDING MARCH 28, AND APRIL 4, 1885.

BATTLE, K. P., assistant surgeon. To proceed to Memphis, Tenn., for temporary duty, March 27, 1885.

MURRAY, R. D., surgeon. Granted leave of absence for one week, March 31, 1885.

BRATTON, W. D., assistant surgeon. To proceed to New York, N. Y., for temporary duty, April 2, 1885.

WATKINS, R. E., assistant surgeon. To proceed to New Orleans, La., for temporary duty, April 2, 1885.

#### APPOINTMENTS.

The following gentlemen, having passed the examination required by the Regulations, were appointed assistant surgeons by the Secretary of the Treasury, April 1, 1885, namely: WILLIAM D. BRATTON, M.D., of South Carolina, and RALPH B. WATKINS, M.D., of Connecticut.

#### AMERICAN MEDICAL ASSOCIATION.

##### SPECIAL TRAIN FROM CHICAGO TO NEW ORLEANS.

At the request of many members of the American Medical Association, the Illinois Central Railroad has arranged to run a special train of Pullman palace buffet sleeping-cars for the accommodation of themselves, their families, and friends who wish to attend the meeting of the Association, which convenes in New Orleans April 25th and continues until May 1st. This also gives a grand opportunity to visit the World's Exposition. The special train will leave Chicago Saturday evening, April 25th, at nine P. M., and run through to New Orleans without change of cars, reaching there at nine A. M. on Monday morning, April 27th, only thirty-six hours en route. The rates for the round trip are as follows: Tickets good for return within fifteen days, \$20.00; tickets good for return within forty days, \$25.00; tickets good for return until June 1st, \$30.00. Those desiring to return by another route, either via Louisville, Cincinnati, or St. Louis, will be provided with tickets at \$5.00 in excess of the above rate. Sleeping-car rates: Chicago to New Orleans, one double berth, \$6.00; Chicago to New Orleans, one single berth, \$4.00. Apply to C. S. Burton, Ticket Agent, 124 Randolph Street, for berths, or address the undersigned.

A. H. HANSON, General Passenger Agent, CHICAGO, April 1, 1885.

#### SOCIETY NOTICES.

GYNÆCOLOGICAL SOCIETY OF BOSTON.—The regular meeting of the Society will be held at No. 19 Boylston Place, on the second Thursday of April at 4 o'clock P. M.

A paper upon the "Treatment of Obstinate Vomiting in Pregnancy" will be read by Dr. A. P. Clarke, of Cambridge. Other papers are expected. Members will please notice the change in the former hour of meeting.

H. J. HARRIMAN, M.D., Secretary.

SUFFOLK DISTRICT MEDICAL SOCIETY. *Obstetric and Gynecological Section.*—There will be a meeting of this Section at 19 Boylston Place, on Wednesday, April 15, 1885, at 7.45 o'clock. The following cases will be presented: Dr. R. B. Dixon, "Is Craniotomy upon the Living Fœtus ever Justifiable?" Dr. R. A. Küngnam, "Anæsthetics in Normal Childbirth." Drs. J. P. Reynolds, Francis Minot, W. A. Dunn, W. L. Richardson, A. D. Sinclair, C. E. Stedman, Benjamin Cushing, and W. C. B. Field will take part in the discussions. JAMES R. CHADWICK, M.D., Chairman. ROBERT B. DIXON, M.D., Secretary.

MIDDLESEX SOUTH DISTRICT MEDICAL SOCIETY.—The annual meeting will be held at Porter's Hotel, North Cambridge, on Wednesday, April 15, 1885, at 11.30 o'clock A. M. Election of officers. Orator, L. R. Stone, M.D., of Newton.

WALTER ELA, M.D., Secretary. CAMBRIDGE, April 8, 1885.

#### DEATH.

DIED, in Edgartown, Mass., March 22, 1885, John Pierce, M.D., M.M.S.N., aged seventy-nine years.

#### BOOKS AND PAMPHLETS RECEIVED.

A Guide to the Diseases of Children. By James Frederick Goodhart, M.D., F.R.C.P. Revised and edited by Louis Starr, M.D. With Formule. Philadelphia: P. Blakiston, Son & Co., 1885.

Reprint of the Proceedings of the Connecticut Medical Society. From 1792 to 1829 inclusive.

Catalepsy. By J. Martin Kershaw, M.D., St. Louis.

The Osteology of Ania Calva, including certain special references to the Skeleton of Teleostomus. By R. W. Shufeldt, Washington: Government Printing-Office, 1885. (Extracted from the Annual Report of the Commissioners of Fish and Fisheries for 1883.)

Intermediate Hospitals for the Treatment of Acute Mental Diseases. By John van Bibber, M.D. (From American Journal of Medical Sciences, January, 1885.)

State Provision for the Insane. By C. H. Hughes, M.D., St. Louis. (Reprint from Alienist and Neurologist, April, 1885.)

Praktische Beiträge zur Kinderheilkunde III. Heft. Die Verdauungskrankheiten der Kinder von Dr. Adolf Baginsky. Tübingen, 1884.

Dental Department of the University of Maryland. Annual Catalogue. Session 1884-85.

Proceedings of the State Board of Health of Kentucky. Quarterly Meeting, March 16, 1885.

The Operative Treatment of Hyperplasia of the Pterus and Vagula, with special reference to the Cure of Displacements. By S. C. Gordon, M.D., Portland, Me. (Reprint from American Journal of Obstetrics, December, 1884.)

## Original Articles.

## RESEARCHES ON THE PHYSIOLOGICAL, CHEMICAL, AND THERAPEUTIC PROPERTIES OF HAMAMELIS VIRGINICA.

BY DR. HECTOR GUY, OF PARIS, FRANCE.

I PROPOSE in this thesis to make a humble contribution to the study of a new medicament which comes to us from America, namely, the hamamelis virginica, or witch-hazel. I shall divide my subject into five parts: In the first I shall include the botanical description; the second will comprehend the medicinal history of hamamelis; the third will be devoted to the chemical analysis; in the fourth I shall study the physiological action; the fifth will be clinical and will comprise the therapeutic applications.

## BOTANICAL DESCRIPTION.

Botanically, witch-hazel has been long known. It was Linnaeus who gave to this shrub the name by which it is distinguished — hamamelis virginica.

The family of Hamamelaceæ (*hamæ*, at the same time; *melon*, fruit, that is, bearing simultaneously both flowers and fruit) contains a few species under the form of trees and shrubs growing in various parts of North America, China, Japan, India, and Persia. The hamamelis virginica (tribe hamamelææ) grows in abundance in almost all parts of the United States, especially in New England, Pennsylvania, and Virginia. It grows in damp woods, blossoming late in the fall, when the leaves are falling, and maturing its seeds the next summer. The witch-hazel is a tall shrub with straight-veined leaves and yellow, polygamous flowers. The fruit is a nut-like capsule not unlike the hazel-nut. The bark, which is the principal medicinal part, has a bitter, astringent, and somewhat pungent taste. According to some too credulous travelers, the witch-hazel possesses mysterious properties, its young twigs being employed by ignorant enthusiasts as divining-rods to indicate the site of metallic veins or underground streams of water. I need not enter further into the description of a shrub so familiar as this must be to the readers of an American journal of medicine.

## HISTORY.

Hippocrates in his "De morbis Mulieb.," book i., mentions, under the name of hamamelis, a fruit, an emulsion of which was given to wet-nurses to increase the flow of milk. It is perhaps in the works of Greek physicians that Linnaeus found the name of hamamelis, which he gave thereupon, perhaps from some fancied resemblance to the American witch-hazel.

In America the hamamelis has long been one of the most popular remedies. It was employed from time immemorial by the Indians, who used it as a sedative and discent in painful tumors and swellings; they pulverized the bark and made poultices of it which they applied to the inflamed parts.

It is only within a few years that the hamamelis virginica has been made the subject of earnest study by American physicians.

The following references to American works and articles in American journals will not be without interest in this connection: —

(1) Durban, in *Atlanta Medical and Surgical Journal*, 1867. This writer attributes to the hamamelis the property of preventing abortion. He claims good results.

(2) R. Hughes, in "Elements pharmaco-dynamic," a homœopathic work, 1871. He urges the use of witch-hazel in chronic inflammations, in varicose dilatation of veins of the pharynx, and in bleeding hemorrhoids.

(3) Ludlam, in *United States Medical and Surgical Journal*, recommends hamamelis externally and internally in ovaritis and in hemorrhagic orchitis.

(4) Hale — "Materia Medica," etc., 1879. Witch-hazel is recommended in all diseases of the venous system, varices, painful and bleeding hemorrhoids, also in hemorrhages generally.

(5) John King — *American Dispensatory*, 1872. Hamamelis virginica is declared tonic, astringent, hæmostatic. Recommended locally in ulcerative stomatitis, in tumors of bad character, in prolapse of the rectum and uterus, and in intractable conjunctivitis.

(6) Scudder and Howe, in *Eclectic Medical Journal*. These eclectic practitioners have found hamamelis very useful in venous states of the mucous membranes, old, torpid, fetid sores, in metrorrhagias, and in hemorrhages generally.

(7) *Philadelphia Medical Times*, September 20, 1883. *New York Medical Journal*, December 8, 1883. In these articles Dr. Musser calls attention to the use of hamamelis in varicose veins and their sequences. Internally in drachm doses of the fluid extract. Astonishing results are claimed.

(8) *American Druggist*, New York, January, 1884. An exhaustive study of this medicament. Cites Dr. Alfred Stillé, James Fountain, and Dr. W. S. Davis as authorities for the internal and local use of this remedy as a powerful styptic, astringent, and venous tonic.

(9) "Essays on new remedies," Dr. René Seruard, Paris, 1881. This writer has made eight trials of hamamelis and confirmed the conclusions of previous experimenters.

(10) *Bulletin Gén. de Théor.*, March 15, 1884. *Bulletin de la Soc. de Théor.*, May, 1884. In these articles Dr. Dujardin-Beaumetz treats extensively of the witch-hazel, to commend its use especially in hemorrhoids; he thinks, however, that there has been great exaggeration as to its therapeutic properties.

The above references comprehend in part the medical literature of this medicament.

## CHEMICAL ANALYSIS OF THE HAMAMELIS.

I fail to find in the writings of American authorities any complete chemical analysis of the witch-hazel. Hughes has noted the presence of tannin. Lea, besides tannin, a bitter principle. On the Continent several chemists have attempted a more complete analysis; Van d'Esp. of Brussels, has found tannin in the bark, existing in the proportion of 10 per cent., a feeble percentage of gallic acid, waxy matters, a red coloring matter, lime, potassa, iron, and an aromatic substance. He arrives at the conclusion that there is no alkaloid in the bark. The aromatic substance which he discovered is, I believe, an essential oil.

As for the leaves, which are much used medicinally in the United States, entering into the preparation of most of the extracts and tinctures (see the last U. S. P.), I have made the following analysis: A certain quantity of the powdered leaves was treated with chloroform; after evaporation, I obtained a solid waxy mass. Then a similar quantity of the powder was placed in a percolator, and sulphuric ether and alcohol were added. The filtrate was evaporated, leaving a residue of astrigent taste, soluble in water, precipitating tartrate of antimony and coloring the ferric salts black. This substance was evidently tannin. Wishing then to obtain an imitation of the fluid extract, I distilled twenty grammes of the powder with one hundred grammes of water; I thus got a *hydrolat* having the characteristic odor of hamamelis, though somewhat weaker than that of the American extracts. This odor becomes stronger with age.

This *hydrolat*, agitated with ether, left after evaporation of the ether a minute quantity of essential oil, greenish yellow, possessing the peculiar "Pond's extract" odor and very volatile. To sum up the results of our chemical investigation, we find in the leaves a waxy matter, tannin, an essential oil, and divers extractive matters.

There are various reasons for believing that in the essential oil (which we regret not having examined further; the small quantity of leaves at our disposal rendering such further study impossible) resides the active principle of the witch-hazel. It is a fact that the fluid extract the most popular, the most vaunted, the most in use everywhere (Pond's extract), which is an aqueous alcoholic distillation, contains no tannin or gallic acid, as we were easily able to prove. What then can be the principle of the therapeutic properties possessed, or supposed to be possessed, by this fluid preparation unless it be the essential oil?

#### PHYSIOLOGICAL ACTION.

No American or French physiologist, as far as I am aware, has performed any experiments on animals with the hamamelis. I have thought that it would be interesting to give the results of my physiological study. My experiments were made in the laboratory of Dr. Dujardin-Beaumetz, in the Hôpital Cochin.

Experiment I. Injection under the skin of a frog's back, by means of a Pravaz syringe, of about ten drops of tincture of hamamelis. There was no appreciable effect manifested, certainly no toxic symptom.

Experiments II., III., and IV., were of similar kind, performed on large, healthy frogs; the injection being made under the skin of the hip. The result, as in the first experiment, was nil.

Experiment V. The interdigital membrane of a frog was moistened and placed in the field of the microscope. After having noted the state of the circulation and the size of the vessels, an injection was made into the upper part of the leg of about two minims of the alcoholic tincture of hamamelis virginiana. The interdigital membrane was examined anew; the state of the circulation did not seem to be much modified. The movement of the blood was

a little slowed in the capillaries and the volume of these vessels seemed diminished.

Experiment VI. The subject of this experiment was a large, healthy frog; the tongue of the animal was drawn from the mouth and fastened to a piece of cork; this was put under the microscope in such a way that a large artery with its accompanying vein was in full view. I then made an injection of ten minims of tincture of hamamelis into the posterior member and watched the appearance of the bloodvessels. At the end of fifteen minutes there was no perceptible effect; I made another injection of ten minims. For more than an hour I continued to watch the bloodvessels, which continued unchanged as before the injections.

Experiment VII. In this experiment, which was made under the same conditions as the preceding, I took care to have in the field of the microscope a network of capillaries; then I made an injection of ten drops of the tincture. Several seconds after the injection it seemed to me that the calibre of the capillaries was a little diminished; but this contraction did not become plainly evident till I had applied locally to the tongue of the frog (under the microscope) a little of the tincture, whereupon the circulation stopped completely.

Experiment VIII. As the results of the previous experiment might be attributed to the alcohol contained in the tincture, I repeated this experiment several times, using not the tincture of hamamelis but the aqueous extract dissolved in water. After the subcutaneous injection I noticed no appreciable result, but on making local applications to the tongue which, as in the previous experiment, was the subject of observation, I obtained a little contraction of the capillaries, but much less marked than before.

I have repeated these experiments from the point of view of modifications of the circulation with other preparations of the hamamelis, notably with the fluid extracts. The results obtained have been much inferior to those which the tinctures gave me.

I have made similar experiments on hares; giving these animals, by mouth and subcutaneously, considerable quantities of various preparations of hamamelis. I have never observed any toxic effect or any modification of the circulation. These experiments seem to me to demonstrate the following facts: Hamamelis is not toxic even in large doses. This conclusion is confirmed by the fact that no case of poisoning by this medicament has ever been recorded.

Hamamelis has no very characteristic action on the vascular system. The phenomena of contraction of the capillaries may be attributed to the tannin in the tincture or aqueous extract; they were not produced when the distilled extract, which is free from tannin, was used.

Nevertheless, from its therapeutic effects there is reason to believe that the action of this medicament is exercised on the venous system and particularly on the muscular coat of the veins. The fact that this drug has no very well-defined physiological properties is not sufficient to warrant its banishment from the materia medica, for many medicines much used in practice have no characteristic physiological action.

## CLINICAL OBSERVATIONS.

I have brief reports of twenty-one cases, thirteen of which were in the service of Dr. Dujardin-Beaumont, two were patients under the care of M. Camperdon, and six were Dr. Serrard's patients; in all the hamamelis was used with varying success.

CASE I. This patient, Charles Martin by name, was afflicted with ulcerous gastritis. Entered the Hôpital Cochin in January, 1884, mainly to be treated for internal bleeding hemorrhoids, which protruded on defecation in the form of little rounded, livid, half-strangulated tumors. These were treated locally by compresses wet with the fluid extract of witch-hazel. The greatest relief followed these applications; the bleeding ceased, and the pain disappeared with the swelling. The patient left the hospital after six days of treatment, almost well of his hemorrhoids, though no better of his gastritis.

CASE II. This was also a case of internal proident hemorrhoids; these were voluminous, painful, and attended with bleeding. Drachm doses of fluid extract of hamamelis were administered every two hours; the same remedy was also locally applied in the form of compresses soaked in the fluid extract. There was sensible amelioration after two days of treatment, and in less than a week both pain and hemorrhage had disappeared. Patient passed from under observation.

CASE III. was also one of bleeding piles; the treatment was similar to that of the above, and was equally gratifying, the patient after eight days of treatment being entirely relieved of the distress and inconvenience from which he had previously suffered.

CASE IV. (also in the service of Dr. Dujardin-Beaumont) was one of varicose veins. A. G. entered Cochin March 15, 1884, for varices of both inferior extremities. These were especially marked in veins of left leg; the dilated and flexuous vessels felt like hard cords and bunches under the skin. The left internal saphenous was remarkable for its varicosities.

March 20th. Fluid extract of hamamelis virginica was administered in teaspoonful doses every two hours. March 22d. The size of the varices is not sensibly modified. They have, indeed, shrunk away a little, but the patient has kept at rest all this time. March 26th. The varicosities of both legs are much less salient; the clusters below the left knee have notably diminished in volume. March 28th. The patient is walking around the hospital, but the amelioration continues. The veins are less tense and voluminous. March 30th. Patient is still better. The varices have perceptibly shrunk. The cordy swellings over the left tibia have almost disappeared. Previously to treatment the patient could not walk without pain; now he can take quite long walks without any inconvenience. Left hospital March 30th. Two months afterward A. G. again presented himself at the hospital for another disease; I examined him thoroughly with reference to his varices. The amelioration had continued; he had been able to pursue his daily tasks without fatigue and pain. There now remained only a few dilatations of trilling nature.

CASE V. was a case of varicose veins with ulcers

over the tibia. The same treatment was pursued, with considerable relief from the pain, though the varices remained unchanged.

CASES VI., VII., VIII., and IX. were also patients in the service of Dr. Dujardin-Beaumont; all were afflicted with varices. In all the hamamelis was given internally, in doses varying from ten drops of the tincture<sup>1</sup> every two hours to a teaspoonful of the tincture or fluid extract three times a day. Case VI. was attended with some positive shrinkage of the varices and relief of the pain. Case VII. seemed to be especially benefited in disappearance of the pain; there was also cicatrization of certain varicose ulcers during the use of the remedy. Case VIII. was a bad one on account of mitral heart disease and dropsy. No benefit from hamamelis. Case IX., varicose veins and ulcers; no benefit.

CASES X. and XI. were patients of Dr. Camperdon. Enormous varices; in Case XI. there were ulcerations. The tincture of hamamelis was given in doses of from five to ten drops at more or less frequent intervals during the day; dose was gradually increased. In Case X., after five weeks of treatment, the engorged tissues began little by little to regain their normal aspect, and the pains disappeared. Dose was increased to twelve drops twice a day. Dr. Camperdon noted certain symptoms which he regarded as toxic, from overdose; these were disturbance of vision, difficulty in walking, and some paralysis, with numbness, of the forearms, hands, and fingers; dose was reduced. The ultimate result was almost complete cure of the varices. Case XI. was a still more unfavorable case for treatment. Enormous varices, ulcerated in places. Tincture of hamamelis (one part of leaves to five of proof spirit), five drops morning and night, for first week; then five drops three times a day for second week, etc. There was gradual improvement, with healing of the ulcers and disappearance of the pain and swelling. After some five weeks of treatment the patient, an unmarried woman of forty, was able, without any inconvenience, to resume her occupation of saleswoman in a store.

CASES XII. to XVI. inclusive were patients of Dr. Serrard. The first case was a Parisian lady, aged twenty, who was suffering from chronic catarrhal pharyngo-laryngitis, with localization of the signs of congestion in the left vocal cord. This was in a varicose condition. Other treatments having failed, Dr. Serrard resorted to the tincture of hamamelis, giving two drops in a teaspoonful of water every two hours. The hamamelis was also employed in the form of inhalation, forty-five drops being added to half a pint of boiling water kept boiling, the patient being required to inhale the vapor fifteen minutes at a time. This treatment was persevered with for a fortnight; there was marked amelioration; the tumefaction and redness of the vocal cord disappeared; the voice recovered from its hoarseness and became natural, so that the patient (who was a vocalist) could sing; there was notable improvement in the condition of the pharynx.

<sup>1</sup> The tincture is made in the following way: Take of witch-hazel bark, one ounce; alcohol, ten ounces. Macerate and filter. Dose, two to five drops, and more. The United States Pharmacopœia of 1883 gives a ready formula for the fluid extract.

geal mucosa and that of the vestibule of the larynx, which were highly injected and swollen. The amendment was both gratifying and permanent.

CASE XIII., a lady, aged thirty-nine, was a sufferer from chronic sore throat; the tonsils being congested and tumefied, the half arches and the pharynx participating in a condition of catarrhal hyperemia which also to some extent involved the larynx. Tincture of hamamelis was prescribed in the same doses as in the previous case. The same inhalation was also practised. A watery solution of the hamamelis was also ordered as a gargle. The amendment was immediate, and cure was gradually effected. In this case benefit was derived from touching the tonsils occasionally with a mixture of 1 part tincture of hamamelis to 2 of glycerin.

CASE XIV. was one of catarrhal conjunctivitis. The hamamelis was given in doses similar to those prescribed in the other two cases, and the patient (an elderly lady) was ordered to bathe her eyes every two hours with a lotion composed of twenty drops of tincture of hamamelis virginica in four ounces of water. This case, which was one of chronicity and great obstinacy, was singularly benefited under this treatment; in fact, in a month's time the patient was discharged cured.

CASE XV. was one of glandular blepharitis in a patient aged fifty, of nervous temperament and arthritic habit. *Symptoms:* since 1880 epiphora, sensation as of grains of sand under the lids, redness of palpebral conjunctival borders, hypertrophy of Meibomian glands. *Treatment:* an eye wash to be used every three hours of tincture of hamamelis half a fluidrachm, warm water a wineglassful. *Results:* almost immediate relief from the uncomfortable sensation and epiphora; ultimate cure. The strength of the lotion was finally increased to tincture of hamamelis virginica two thirds, warm water one third.

CASE XVI. was one of chronic parenchymatous metritis, in a married woman aged thirty. *Cause:* imperfect involution following an accouchement in 1875. *Symptoms:* easily provoked fatigue, pelvic pain radiating into stomach and back, shooting down thighs, heavy pressing weight on walking, no ease except when lying, dyspeptic troubles. *Vaginal examination:* vaginal cul-de-sac free, uterus enlarged and heavy, low down in pelvis, in anteversion, the cervix resting posteriorly on the vaginal floor. The speculum shows the neck large and of violaceous appearance; the two lips oedematous and largely everted (areolar hyperplasia). *Treatment:* every morning to the os and cervix a tampon of wadding saturated in a mixture of 1 part tincture of hamamelis, 2 parts of glycerin. This tampon was packed in the vagina and was kept in till the next morning. The tincture of hamamelis was also used externally as a liniment to the back. This treatment was continued nearly two months. *Results:* slow and effectual amelioration; reduction of the hypertrophy, the uterus the last week of treatment having diminished in size to normal; abatement and disappearance of the pain and reflex phenomena.

CASE XVII. was a patient in the care of Dr. Dujardin-Beaumetz. Disease, metro-peritonitis. Entered Hôpital Cochin February 21, 1881. There had been a previous history of a painful abdominal

affection, attended with vomiting and constipation and metrorrhagia.

*Present state.*—Pain in hypogastrium and left iliac fossa, radiating to the loins and thighs. *Vaginal examination.*—Heavy globular uterus, with neck effaced and carried to the left; cul-de-sac (except the posterior) obliterated; fixity of the uterus which by abdominal palpation is felt above the pubes. Reflex gastric and intestinal disturbances were marked.

The tincture of hamamelis was administered internally with no relief whatever.

CASE XVIII. was one of chronic parenchymatous metritis, under care of Dr. Serrard. It was complicated with endometritis with ulceration of the cervix, consecutive to arrest of involution after confinement. The treatment was like that of case XVI. and was attended with equally successful results; it should be remarked, however, that mineral sulphur waters were used at the same time, and "Scotch pin douches" (*douches à épingles écossaises*) over the lumbar region.

The three following cases were in the service of Dr. Beaumetz. The first was one of chronic enteritis; from three to twelve mucous, sanguinolent stools a day, with pain. After failure of other remedies, hamamelis was tried in the form of two-grain pills of the solid extract; dose: two pills a day. This dose was increased to nine pills a day; the result was nil.

CASE XX. was one of blennorrhagic orchitis. Tincture of hamamelis was given in ten-drop doses every two hours with rapid diminution of the size of the testicle and disappearance of the pain.

CASE XXI. was one of hæmoptysis in a patient in the last stage of phthisis. Tincture of hamamelis was given in teaspoonful doses every two hours. There was at first amendment under the treatment, but the hæmoptysis soon returned and the patient succumbed to the excessive loss of blood. The autopsy revealed a cavity with a miliary aneurism, whose rupture had caused the fatal hæmorrhage.

#### ANALYSIS OF THE CASES.

The first three cases pertain to hæmorrhoids. Has the hamamelis any special action in these cases? Certain American writers have claimed it as a specific. I am not prepared to indorse this claim, but the topical effects of the medicament seemed to be good in these three cases, an amelioration following the very first application. It is, however, presumable that whenever there is a mechanical obstacle to the circulation in the veins of the rectum, and whenever the hæmorrhoidal tumors are accompanied with anal spasm, the hamamelis will be without efficacy. In observations II. and III. the external employment of the hamamelis was associated with its internal administration. I am inclined to think that there is a good deal of testimony in favor of the internal use of the witch-hazel in piles.

In the eight following cases we have to do with varices. The employment of hamamelis has not given results as conclusive and as certain as those announced by Dr. Musser, of the Philadelphia County Medical Society. Moreover, the appreciation of facts at their just value is here very difficult,

and it is easy to attribute to the medicine effects which are due to rest. These cases are almost always persons easily fatigued, whose occupation requires prolonged standing, and whose varices, in consequence, take an exaggerated development by the force of gravity. A few days of rest in the hospital suffice to calm the pain and render the varicose swellings less apparent. This is what case VI. taught us. The patient who after ten days of treatment was considerably better went walking about the hospital; the next day the varices were as bad as ever.

Case IV., however, seems to me an exception. This patient had had varices for nearly ten years. After ten days of treatment the enormous varicose veins were quite perceptibly shrunken and the knotty tumor of dilated veins over the tibia had almost disappeared. The benefit in the case of this patient was lasting, as was shown by the fact that two months afterward, on returning to the hospital, he was found to be entirely well of his varices.

In Cases V. and VI. no marked benefit was noted. Case VII. (varicose ulcers) was attended with notable amelioration.

Case VIII. is not conclusive; the varicosity was complicated with oedema of the lower extremities from mitral valvular disease.

In Case IX. no amelioration.

In Cases X. and XI. the use of the hamamelis seemed to be attended with fairly good results.

The witch-hazel does not, then, seem to have any constant action in this affection. In some cases it seemed to do good; in others the effect was nil. It seems to be more beneficial when the veins are simply dilated, and little if at all hypertrophied. There is, however, a fact to which I wish to call attention, namely, to the decided analgesic action of hamamelis in varices, as well as in hemorrhoids and pharyngeal, laryngeal diseases, etc., and this effect is often observed even when no perceptible amount of shrinkage is seen in the enlarged veins or other swellings.

Cases XII. and XIII. show the advantage which may be derived from the internal and local use of tincture of hamamelis in chronic laryngeal and pharyngeal congestions with varicose dilatations of the veins of the region.

Cases XIV. and XV. illustrate the de-congesting action of hamamelis in conjunctivitis and blepharitis. Hamamelis has also been employed with success in two cases of chronic parenchymatous metritis, as seen in the report of cases XVI. and XVII. Its efficacy in this disease is especially noticed in the first phase of the disease, when the uterus is congested and engorged and the cervix is voluminous, deformed, patulous, but not indurated.

Case XIX. did not seem to be a fair case for trial of the medicine in chronic enteritis. The disease was probably tuberculous and little amenable to therapeutic agents.

Case XX. (hemorrhagic orchitis) seemed to be remarkably alleviated and helped toward a favorable issue by the internal use of hamamelis. The analgesic action was almost instantaneous.

It remains to speak of the hemostatic properties of the witch-hazel. Case XXI. is not a good test

case; the patient was in the last stage of phthisis, and no medicine could have stayed the aneurismal rupture. In America good results have been reported from the hamamelis in hæmoptysis. In the two following cases, communicated to me by an eminent Paris physician, the benefit was unquestionable. The first was a hæmophilic infant, brought to death's door by repeated attacks of epistaxis. The internal and local use of hamamelis promptly arrested the hæmorrhages the first and every succeeding time.

The second case was of metrorrhagia from uterine fibroids. The internal use of fluid extract of hamamelis completely controlled the hæmorrhage and proved a boon to the patient.

#### CONCLUSIONS.

(1) Hamamelis Virginica is not toxic. Employed in very large doses it produces no symptoms of poisoning in the inferior animals. It does not appear to be toxic to man, despite the fact recorded by Dr. Camperdon, concerning which there would seem to have been some mistake.

(2) It does not appear to have any special physiological action on the vascular system, heart, veins, or arteries.

(3) We have not noted any alkaloid in the bark or leaves; the active principle is probably the essential oil.

(4) Therapeutically hamamelis has an uncertain action. It has, nevertheless, given good results in certain cases of hæmorrhoids. As a hæmostatic its action has seemed demonstrated in some circumstances. The results obtained in varices are not conclusive.

(5) Hamamelis Virginica does not seem to merit the enthusiasm bestowed on it by certain American physicians. It has no clearly defined special action. At the same time, in certain cases, its employment may be attended with success.

#### NOTE ON A HITHERTO UNRECOGNIZED FEATURE OF THE TEGMENTUM.

BY E. C. SPIZKA, M.D., OF NEW YORK.

THE study of a series of microscopic sections, prepared from the brain of a kitten, in which I had succeeded in inducing complete atrophy of the left cerebral hemisphere, left thalamus, and optic tract (the animal being killed three months after the necessary operation), revealed the following striking and important conditions:—

(1) The anterior commissure is present, and of about half the size of the same part in a normal kitten of the same age. (2) The detachment of fibres which connect the commissure with the thalamus is well developed on the right side and absent on the left. In Fuchsin-stained sections this difference is particularly well marked. (3) The continuation of the commissural fibres ventro-caudal is present on the left side and absent on the right side; owing to the secondary atrophy on the left side of the other structures—particularly the tracts—it comes out with abnormal distinctness. (4) The bundle in question moves along the side of the central tubular gray, gradually approaching the

ventral aspect of the brain axis, and, at the same time, nearing the median raphe. It ultimately moves ventral of the posterior longitudinal fasciculus of the tegmentum, closely underlying it, and in immediate contact with the gray intercalation of the raphe. In the level of the posterior corpora bigemina this bundle is so well demarcated as to be differentiable from neighboring structures by the naked eye. (5) No field of approximate size, structure, or distinctness is found on the right side. To the naked eye no fasciculus is visible; under the microscope a few strands are found in a more lateral situation, which leaves it doubtful whether they are truly homologous. (6) The relations of the developed bundle of the left side change as it continues caudal; it is no longer as compact in the caudal half of the pons, and appears to receive admixtures of fibres from other sources, or, possibly, to exchange fibres with other systems. Still, even down through the oblongata, while the corresponding field of the right side begins to appear, it fails to equal that of the left side. In the cephalic part of the pons it is not so close to the posterior longitudinal fasciculus, more ventral, and instead of being shaped like a square field in section, is elongated, with the long axis of the field parallel to the raphe, and a short distance removed from it. Here the difference between both sides is as marked as in the level of the posterior pair of the corpora quadrigemina.

From these observations it is evident that the posterior commissure is a true decussation, uniting the thalamus of one side with the tegmentum of the other, and that the decussation is "total," or nearly so. Meynert claimed such a connection, but was unable to demonstrate it to the satisfaction of later writers, several of whom are still inclined to regard it as a true commissure, uniting symmetrical ganglia. Forel denies that a connection of the posterior commissure with the tegmentum is demonstrable.<sup>2</sup> I believe that the atrophy of the denied fasciculus, in my experiment, on the side opposite to the removal of the thalamus, is the first clinical demonstration of its course, by a method which is universally considered reliable, at least with regard to its positive results; while the true position of the crossed fasciculus in the tegmentum is for the first time demarcated. The influence of the removed hemisphere may safely be disregarded, as the isolated removal of this part of the brain does not affect the posterior commissure; the atrophy of one branch of the cross must be referred to the atrophy of the thalamus, and to it alone.

In the cat it is possible to trace the field in question through the tegmentum to the cord by the embryonic (Flechsig's) method, and thus the connection of the thalamus with the cord, through the crossed thalamo-tegmental tract, as I propose to term the fasciculus demonstrated in my experiment, thus becomes established.

In conclusion, I may state that the section of this brain axis in the level of the posterior pair of the corpora quadrigemina exhibited a remarkable picture. On the right side the pyramid tract, cortex lemniscus (of Von Monakou), direct thalamic bundle, and posterior longitudinal fasciculus were

normal, and only the crossed thalamo-tegmental bundle atrophied; on the left side this was exactly reversed: the pyramid altogether absent, the cortex lemniscus scarcely identifiable, the direct thalamic bundle<sup>3</sup> a shrunken field, and the posterior longitudinal fasciculus greatly diminished; the crossed thalamo-tegmental bundle was, however, well-marked—a convincing proof of our power to produce distant atrophy of nerve tracts in their natural course.

## REPORT ON THEORY AND PRACTICE OF MEDICINE.

BY GEORGE B. SHATTUCK, M.D.,

Visiting Physician, Boston City Hospital.

### DIAGNOSIS OF CANCER OF THE STOMACH.

THE not infrequent difficulties and uncertainties of diagnosing gastric cancer forms the subject of a communication by Dr. Dujardin-Beaumetz to the Société des Hôpitaux.<sup>1</sup> The uncertainties rest upon three causes: (1) The vague value of the word cancer, (2) the slow development of some cancerous changes of the stomach, and (3), especially, the more exact knowledge obtained of late of another pathological condition of the stomach,—dilatation with thickening of the walls.

(1) Pathology distinguishes the so-called cancerous tumors anatomically, and clinical medicine attempts to divide them according to their course and development, an attempt which is more successful with external than with internal growths. Many morbid growths are still included under the term cancer which have nothing in common except their incurability and fatal termination. This is particularly true in regard to the stomach, where the situation, as well as the character of the lesion, makes a great difference in the course and termination of the case. A small growth at the pyloric, or even at the cardiac, extremity of the stomach may entail pronounced symptoms and rapid death by the disorders in nutrition to which it gives rise, and through its own malignant character.

(2) On the other hand, there are cancerous growths of the stomach analogous to those which attack the breast and the uterus which run such a slow course that they are borne for a series of years without producing any serious change in the general economy.

In support of this position Dujardin-Beaumetz reports a case in which he found cancer of the stomach (confirmed microscopically by Cornil) in a patient who ten years before had begun to suffer from the characteristic signs, including bloody vomiting; at that time a diagnosis of cancer was made, but the patient improved to such an extent upon a regulated milk diet that he was able to resume work, though interrupted by occasional relapses. When seen, during one of these, the year before death, it was suspected, on account of the duration of the case, and notwithstanding the patient's more than seventy years, that chronic ulcer or dilatation must be the cause of the trouble. Beaumetz regards this

<sup>1</sup> This is situated lateral in the tegmentum, in contact with the angle formed by the (identical) union of the cross-section of the descending trigeminal root and the posterior longitudinal fasciculus.

<sup>2</sup> Gazette Hebdomadaire, 31, 1884.

<sup>3</sup> Stricker's collection, vol. II.

<sup>4</sup> Forel, "Die Haube," Archiv. f. P. Gehirne, vii.

case as conclusive and by no means unique, and think the statistics of Brinton, Lebert, and De Valéix, which place the average duration of cancer of the stomach at thirteen months, the minimum at one month, and the maximum at three years, stand in need of revision.

(3) The third source of obscurity is dilatation of the stomach, and by dilatation Beaumetz does not refer to the relaxed and atonic forms described by Bouchard and by Sée and Mathien,<sup>2</sup> but to a form of dilatation accompanied by *thickening* of its walls, which is generally consequent upon a chronic inflammation of the different coats. In this affection the stomach is sometimes enormous, and occupies the whole abdomen. Neither sex, age, a cachexia, nor the local symptoms can be appealed to for a differential diagnosis. This condition is more frequent, in about the same proportion as cancer, in men than women; most of these cases occur in individuals over forty years of age. When not controlled by active and proper treatment (washing out) they are accompanied by profound disturbances of nutrition, producing a cachexia fully as marked as any observed in cancer, disturbances leading to a fatal termination. Moreover, the venous thrombosis, considered by Trousseau pathognomonic of cancer, may accompany this condition; the general symptoms of pain, coffee-ground vomiting, and tumor may be, and not seldom are, present in this form of dilatation and absent in cancer.

To overcome these sources of obscurity, distention of the stomach by gas, thereby bringing irregularities into prominence; examination of the gastric juice and determination of the amount of acid; and a quantitative examination of the urea secreted by the kidneys, have all been suggested and practised. Of these Beaumetz finds the third, suggested by Rommelaere, of Brussels, the only one offering as yet much guaranty of practical success. Rommelaere found in a number of cases of cancer of the stomach and of other organs that the excretion of urea averaged about nine grammes, whereas in a number of cases of dyspepsia and gastric ulcer the minimum was seventeen, and the maximum thirty-five, grammes of urea.

Beaumetz applied this method in his hospital service with the following result: four cases of probable cancer of the stomach yielded each a daily maximum average of six, and a minimum of four, grammes of urea as the result of nine days' observation; one case of ulcer yielded a daily average of twenty grammes; five cases of *gastrites ulcéreuses* a daily average of from twenty to twenty-six grammes.

This method may be made of service in differential diagnosis in hospitals and occasionally outside; but the varying quantity of urea secreted by any individual in health or disease, the details of the quantitative examination, the possible deficiency of urea in dilatation accompanied by deranged nutrition complicate the applicability of such a test.

#### INOCULATION OF TUBERCULOSIS.

Tscherning<sup>3</sup> (*Hospitals-Tidende*, December 17, 1881) records an interesting and instructive case of

accidental inoculation in the hand with tuberculosis. The patient, a strong, healthy girl, without family tendencies, had been in the service of a gentleman who died from rapid pulmonary phthisis, and whose expectoration, toward the end of life, was an almost pure culture of tubercle bacilli in pus. A few days before his death, end of July, the girl wounded the volar surface of the first phalanx of the left middle finger with a piece of china from a broken spit-cup used by the master.

A fortnight later she presented herself to the reporter with an incipient paronychia. The symptoms subsided somewhat on suitable treatment; there was no suppuration, but in the subcutaneous areolar tissue a small lump scarcely as large as a split pea was detected, which remained stationary for some little time, though accompanied by oedema and moderate soreness of surrounding tissues. The end of August a small incision was made, and the lump, composed of granulations, scraped out, the wound healing by first intention under iodoform and corrosive sublimate. The beginning of October patient complained of pains on flexion of fingers; the subcutaneous tissue of the phalanx and adjacent part of the palm of hand were slightly swollen; the mobility of the finger was diminished, and it was the seat of moderate pain and sensitiveness, and at this time two swollen glands were detected in the elbow and two in the axilla of the same side.

On the twenty-first of November the swollen glands were extirpated, the finger was exarticulated at the metacarpo-phalangeal joint, the palmar skin was slit open, the tendon with its swollen sheath was removed up to the middle of the hollow of the hand, and the subcutaneous granulations present were cut out with scissors or scraped out with a curette. The operation was performed and the wound was dressed antiseptically. It healed by first intention in eleven days.

The pathological changes found were as follows: The sheath of the tendon was closed with pale granulations. The serous cover of the tendon was studded with petechiæ. No pus, cheesy masses, articular or bone affection were found. Under the microscope, the granulations, after hardening in alcohol and staining with picrocarmine, showed very numerous elementary tubercles, sometimes with cheesy degeneration of the centre, numerous large cells, and beautiful partly central giant-cells. The extirpated glands looked to the naked eye like common hyperplastic glands without pus or cheesy substance. The microscope revealed hyperplasia due to large cells with interspersed elementary tubercles. In all the sections, both of the granulations on the sheath of the tendon and of the lymphatic glands, were found distinct tubercle bacilli, demonstrable by means of Chediak's staining method. They were partly imbedded in epithelioid cells or giant-cells, partly situated at the confines of the microscopical necrobiotic spots. Most frequently they were isolated, but here and there two or even three were found together, forming a more or less open V. Often they contained spores.

The reporter adds that these conditions correspond entirely with what he has found in about thirty cases of local tuberculosis (arthritis, tenositis, spondylitis, pyogenic membranes, lymphatic glands, testicles, tongue, pyelonephritis).

COMA, RESEMBLING THE SO-CALLED "DIABETIC COMA,"  
WITHOUT DIABETES. DYSPETIC COMA.

As an illustration of the views advanced by Frerichs<sup>4</sup> and Senator,<sup>5</sup> a summary of which has previously been given in these reports,<sup>6</sup> and in honor of the late Professor Frerichs's 25th year of professional service, Litten and Riess have reported cases which they have observed. Litten<sup>7</sup> reports five cases with a peculiar combination of symptoms resulting from self-intoxication from dyspeptic conditions which he terms "dyspeptic coma." Of these patients two were small children and three were men of thirty odd years of age, in previous good health. Several days of prodromal symptoms, accompanied by gastric disturbances, preceded the condition of coma, which in all was light, and never amounted to full unconsciousness. The characteristic fruit-smell of the breath was present, and also the red reaction of the urine, which was somewhat diminished, to chloride of iron; there was neither sugar nor albumen. On the other hand, the typical deep breathing of "diabetic coma" was not observed. The pulse was small and the heart weak. In two or three days this state of things gradually disappeared, and the patients returned to their usual health. That the symptoms of intoxication described were the result of indigestion seems probable, but whether by the retention of normal products of fermentation or the formation of abnormal products remains more uncertain.

Riess<sup>8</sup> reports seventeen cases, with the typical respiration of "diabetic coma," but without the burgundy-red reaction to the urine, occurring in somewhat different diseases, namely: (1) eight cases in anæmia, of which three were extreme simple anæmias, two were probably pernicious anæmias, and three anæmias resulting from previous losses of blood; (2) five cases in anæmias complicated with renal disease; (3) four cases in cancer of the stomach and liver. Riess considered the coma in his patients due to the condition of the blood, and dwells on the change in quality rather than on the change in quantity as a cause. The change in blood pressure is more likely, however, to account for sudden coma than the diminution in red blood-globules, and in Kussmaul's coma the small, feeble pulse is almost invariably present. Riess found no ground to suspect self-poisoning from the digestive tract as a cause of the coma in his cases.

CONSEQUENCES OF EXTIRPATION OF THE SPLEEN.

Mosler<sup>9</sup> sums up the results of extirpation of the spleen in a large number of dogs and other animals as follows: (1) The spleen is not essential to the life of animals. (2) After extirpation, as well as after artificially produced atrophy of the spleen, its function will be assumed by the other lymphatic organs. The marrow of the bones seems to play an important rôle in this; striking changes, similar to those observed in leukaemia, are observed therein long after extirpation of the spleen. Hyperplasia of the lymph glands is not always found. (3) The

vicious activity of the lymphatic organs is not always sufficient, as a changed condition of the blood is found, especially in the first months after extirpation. Hence one may conclude the spleen has a direct influence upon the formation of the blood, and that by creation of white as well as of red corpuscles. (4) Extirpation of the spleen produces no effect upon gastric and pancreatic digestion.

MALIGNANT (SO-CALLED ULCERATIVE) ENDOCARDITIS.

Dr. William Osler, late of Montreal, now of Philadelphia, has just delivered the Gulstonian lectures in London on this interesting subject. His views are but little modified from those previously published, as the result of his observations and studies in Montreal, in a paper contributed to the *Archives of Medicine*, an abstract of which was given at the time in these reports.<sup>10</sup> The lectures<sup>11</sup> before the Royal College of Physicians are an amplification of that paper, but reflect the study of a larger number of cases. In that paper Dr. Osler analyzed fifty-seven reported cases, contributing seven of his own, with autopsies. Since then he has collected and analyzed two hundred and nine cases. The old term "ulcerative" he still thinks should be rejected as misleading and inadequate, "as there may be no actual loss of substance and no more destruction than occurs in the ordinary form; and, on the other hand, there may be great destruction and ulceration from causes of an entirely different nature." For the term "infectious," which he then proposed, he now would substitute the adjective "malignant," as less indicative of the mode of origin of the disease.

In fact, the last word upon the subject still leaves it quite undetermined whether we may regard the symptoms and appearances grouped under this title as a separate disease, or simply as an intercurrent complication of a variety of pathogenic conditions, and it is certain that, notwithstanding the not infrequent mycosis of the cardiac valves, no specific organism has as yet been identified with "malignant endocarditis."

In fully one half of the cases on record the diagnosis was made postmortem. Dr. Osler acknowledges "that the protean character of the malady, the latency of the cardiac symptoms, the close simulation of other disorders combine to render the detection peculiarly difficult," and that it is no disparagement to the many skilled physicians who have put their cases upon record that the diagnosis is not more often made during life.

THE DIAGNOSIS, Dr. Osler thinks, is easy enough in the group of cardiac cases in which the disease attacks a patient the subject of chronic valvulitis, but even then the simple warty endocarditis accompanied by slight fever which not infrequently attacks sclerotic valves, and the irregular pyrexia arising from other causes, — local suppuration, cellulitis, etc., — in chronic heart disease must be excluded.

In rheumatic fever, if with the occurrence of a murmur the symptoms become aggravated and assume a typhoid or pyæmic type, the recognition of the complication should be easy; but even here the

<sup>11</sup> Lancet, British Medical Journal, March 14, 21, 28, 1885; Medical News, March 21, 28, April 4, 1885.

onset of severe head symptoms must be carefully distinguished.

In pneumonia a prolongation of the course, with the supervention of typhoid or septic symptoms, should lead to a careful examination of the heart.

"The greatest difficulty is met with in those acute cases resembling the malignant forms of the fevers: here the affection may simulate typhoid, typhus, cerebro-spinal meningitis, or even hæmorrhagic small-pox. Even with the detection of a heart-murmur the judgment may have to be suspended, and many cases die with the general symptoms of profound blood-poisoning before the development of any special features upon which a diagnosis could be based.

"From typhoid fever, with which the cases are most often confounded, the mode of onset, the pyrexia, and the abdominal symptoms offer the chief points for discrimination. The onset of severe endocarditis is more abrupt, not so often preceded by a period of failing health and progressive weakness. In a large number of cases cardiac pain or oppression and shortness of breath are mentioned as early symptoms. The fever rarely presents, in the early days of the disease, the regularity of typhoid, and from the outset may be very high. A sudden fall to the normal, or even below, may occur; indeed, irregular pyrexia is one of the most important diagnostic signs. The combination of diarrhœa, abdominal distention, and a rose-colored eruption points strongly to typhoid fever. The rash, when present, is usually petechial, a rare circumstance in typhoid fever. The development under observation of pronounced murmurs, particularly of aortic and regurgitant, is most suggestive of malignant endocarditis, and the occurrence of emboli would be a positive confirmation. Rigors rarely occur in typhoid fever, while they are common in endocarditis. It is well, however, to bear in mind that, in many of the most severe cases, death may occur, as in any of the infective disorders, without the development of the special symptoms necessary for a diagnosis.

"Many of the cases present the clinical features of pyæmia, a condition which may actually exist, dependent upon the ulcerative lesions on the valves; and here the diagnosis lies between an ordinary septic infection from a wound or auto-infection from a primary endocardial inflammation.

"It is interesting to note the similarity of those cases of acute endocarditis in which death occurs in a few days, without the development of any other than the valvular lesion, with those instances of rapidly fatal acute periostitis and necrosis, and also with those cases of malignant septic infection from a slight external lesion.

"It seems strange that difficulties should arise in the diagnosis between malaria and malignant endocarditis, but the records of cases plainly show that for weeks or months a condition of intermittent pyrexia may occur, simulating every type of ague. The paroxysms in regularity, in order of sequence, and in the accompanying general conditions may fulfil every condition of a quotidian or tertial intermittent; and the development of cardiac symptoms, with breaking of the pyrexial type, may alone determine the nature of the case."

## Hospital Practice and Clinical Hemoranda.

### A CASE OF EMPYEMA.

BY JOHN EDWIN WALKER, M.D., OF THOMASTON, MAINE.

On the fourteenth of July last I accompanied J. B. Walker, M.D., who was called to visit a young man said to be sick with pneumonia. The history of the case, as obtained from the patient and friends, was as follows: F. H. I., aged twenty-six, unmarried, driver of a milk-cart, previously well, but on the seventh of February, while at a skating-rink, got chilled. In a few days a pneumonia—so called by the attending physician—was developed; he was confined to his bed some five or six weeks; he then became able to walk about his room, but still had a severe cough. During his apparent convalescence he had his hair cut, and immediately he was again confined to his bed. The cough which he had had from the onset of the disease became more frequent, until at last he was unable to sit up without coughing incessantly; he was also unable to lie upon his left side or back. The condition of the patient at the time we visited him was as follows: Countenance pale and anxious; pulse 145; temperature 103°; extreme emaciation; any exertion whatever caused cyanosis and dyspnoea; on the right hip there was a bed sore the size of one's palm. By measurement we found an increase in the size of the affected side (right) of 4.5 inches, and there was bulging of the intercostal spaces. The heart was displaced to the left two inches or more; below the free borders of the ribs there was a fulness, with more or less downward displacement of abdominal viscera. There was absence of motion on the affected side, while on the unaffected side there was an increase in the force and frequency of the respiratory movement. On percussion, with the patient in the sitting position, there was complete flatness from base to apex anteriorly, and posteriorly on the affected side. Palpation showed entire absence of vocal fremitus, and auscultation complete absence of all vocal and respiratory sounds in the same affected side. There was marked exaggeration in the vesicular breathing of the unaffected side. A diagnosis of pleuritic effusion was made, an operation was advised, and the following day was performed by Dr. Walker, assisted by myself. The aspirator needle was introduced into the fifth intercostal space a little in front of the axillary line, and the fluid, which proved to be pus, was allowed to flow, until there was a sense of constriction about the chest; one pint was removed at this time. On the second day after this the needle was again introduced, and a pint and a half of pus was removed. Two days after this a trocar was introduced, removing three and a half quarts of pus, when the patient complained of a sense of constriction about the chest, and the instrument was withdrawn. The relief following this operation was great. It was then decided to make a free incision and insert a drainage-tube. Three days later an incision was made into the thorax at the fifth intercostal space, immediately in front of the axillary line, and a silver drainage-tube inserted. At this

time three quarts of pus were evacuated, when the patient complained of thoracic constriction and there was paroxysmal coughing, and the tube was then closed. Subsequently the tube was left open permanently, and the purulent discharge was very copious. The patient steadily improved, and fifteen days after the operation—the discharge having ceased—the tube was withdrawn. The opening closed at once. Convalescence was rapid, and the patient, last November, considered himself as well and strong as ever.

Every operation was performed with antiseptic precautions and antiseptic dressings were used.

## Reports of Societies.

### CLINICAL SOCIETY OF THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL.

MEETING OF JANUARY 17, 1885. DR. A. H. SMITH in the chair.

#### DIABETES MELLITUS.

DR. SATTERTHWAITHE remarked, in opening the discussion upon diabetes mellitus, that our ideas of glycosuria might be grouped about the four clinical phenomena that characterized the disease, namely, inordinate thirst, excessive appetite, bodily emaciation, and glucose in the urine, the latter being always the prime symptom that decided the nature of the disease. The ordinary clinical tests established the presence of sugar if it existed in any quantity; on the other hand tests that indicated only a minute quantity of sugar had little clinical value, as the normal urine contained a small proportion of grape sugar. Sugar was present in the liver and any of the carbo-hydrates, or even in some instances the fats and albuminous substances might be required for its production. The occurrence of sugar in the urine might be explained by studying the results of Claude Bernard, Schiff, Landois, Klebs, Pavy, Eckhard, and others, who had shown that injury to the sympathetic filaments, either at their roots or in any part of their course, or of the cervical or thoracic ganglia, would cause glycosuria, or any agents such as curare, chloroform, ether, chloral, amyl-nitrate, or carbonic oxide, that would temporarily paralyze these nerves, might be the aetiological factors. The peripheral nerves such as the pneumogastric or sciatic might also by reflex action accomplish the same result, as many experimenters had shown. In all these cases it was believed that vaso-motor paralysis of the hepatic vessels took place. With the increased current of blood supplied to the organ it was believed that hyperoxidization took place.

Injury to the parenchyma of the liver was also shown to induce glycosuria, and injection of unusual amounts of saccharine material or of material capable of conversion into the former was often sufficient to start the trouble. Abnormal action of the pancreas was also thought to induce this condition and the morbid changes found in the organ at post-mortem seemed to sustain this view.

The pathological findings were also in accord with these ideas, for though the liver had been found

diseased in about one half the cases, in a large number the nervous system was found to have been involved in such a manner as to sustain the physiological experiments. Thus Klebs had reported a case in which he found unusual dilatation of the hepatic and splenic arteries, and Recklinghausen had made somewhat similar reports. Though Dickinson's description of the microscopic appearances in the brain did not imply anything distinctive, Richardson had made an important contribution to the pathological anatomy by finding an ossific growth pressing on the pons; while Dompoling observed a tumor the size of a nut occupying the whole of the right half of the medulla, and Ponocklo detected an infiltration of the cervical ganglia with connective tissue, so that the nerve fibres and cells had virtually disappeared. Silver and Harley found lesions of the cord and pneumogastric respectively.

The change in the kidneys was a prominent phenomenon. Rokitsansky observed it in sixty-seven per cent. of his diabetic postmortems, but there was hardly any doubt that this metamorphosis was secondary, as indeed our clinical experience demonstrated. It was not to be expected that the organs could do an increased amount of work continuously and not show the effects of it, and this they usually did by their increased size and the swollen and otherwise altered condition of the parenchyma.

Though the lungs had been found diseased in a large proportion of the postmortems, in about fifty per cent. tubercular (Griesinger), it was not certain that this condition preceded the diabetes; indeed such statistics as were at hand appeared to show that all pulmonary lesions, whether of pneumonia or phthisis, were concurrent and late features of the malady.

In considering the aetiology of diabetes it was plain, at the outset, that it was found most frequently in persons of neurotic constitution and especially in families where there was insanity or epilepsy. The exciting cause was frequently some violent impression upon the nervous system, such as might be occasioned by mental emotion or a physical injury, sexual abuse, possibly alcoholism or the opium habit. Whether exposure to cold or malarial infection were to be classed among the causes was not clear. It was most frequently present in males who had passed middle age.

The symptomatology of the disease was incomprehensible unless we adopted the three subdivisions of temporary, mild, and severe forms, when it would be found that the cases naturally fell under one or the other head. In a case of temporary glycosuria while we might have inordinate thirst, increased appetite, and some diminution in weight, all the symptoms yielded readily to a restricted diet and a moderate amount of medicine. The disease once arrested was practically cured. When the attack followed the taking of chloroform or ether it was even less severe and hardly disturbed the economy to an appreciable degree. In the mild form the same treatment reduced the disagreeable phenomena to a minimum, and the patient continued to enjoy fair health and might have a complete disappearance of the trouble for a considerable length of time. In the severe forms, however, the disease was never

under complete subjection, although a restricted diet would always modify some of its most unpleasant features; still the patient gradually failed and sooner or later some complication would be noted, such as nephritis, phthisis, or a cardiac disorder, gangrene or carbuncles, etc., that ended his life often in a most unexpected manner. Usually death was brought about by uræmia, possibly by acetæmia in a small per centage of the cases, but of this there was every reason to speak guardedly.

Of the twenty or more tests for sugar there were few that could be recommended except Trommer's and Fehling's for qualitative analysis, and the volumetric, differential density test (Roberts's) and George Johnson's for estimating the quantity. Fehling's had gradually superseded Trommer's because it demonstrated a smaller quantity of sugar and was less liable to misrepresentation in the hands of inexperienced persons. It would probably be best to mix the several ingredients freshly each time it was used, as the preparation as sold in the shops was unstable. The formula given for this purpose by Flint, Jr. and Bailey were the best. The volumetric method (with Fehling's standard solution) was theoretically the best because it ensured accuracy and was rapid. Practically it was difficult to tell at what moment the blue color was discharged and the suboxide of copper deposited. Great errors might therefore be the result, and the apparatus was somewhat elaborate and expensive. The most accurate in ordinary clinical work was Roberts's, but it was necessary for the fermentation to proceed at a moderately high temperature (about 70°) and even then it required twenty-four hours. The apparatus was, however, inexpensive and simple, a good urinometer being the thing of prime importance. Dr. George Johnson, of London, had a method which theoretically superseded them all for quick work and accuracy, as the apparatus could be carried in the pocket and the quantity of sugar estimated while at the bedside. It was a color test and the quantity of sugar was determined by comparing the saccharine urine, after the application of picric acid and potash, with a standard solution of iron and ammonia. The fact that a large number of persons could not distinguish the finer shades of color upon which the test depended prevented its being generally accepted.

One of the first principles to be laid down in the treatment of glycosuria was that the patient should adhere rigidly to a restricted diet from which all sugar and starchy food were excluded, and then each case should be treated according to its special indications. Thus neuralgic pains would be best combated by opium or its alkaloids. Colic, as recommended by Pavy, had met with general favor because it was an agreeable sedative and did not materially increase the constipation that was a marked feature of glycosuria. But other sedatives, such as bromide of potassium, had also been found useful, as well as curative, when given in connection with a restricted diet. Ergot and ergotine in physiological doses had also aided materially as would be supposed by a study of the ætiological factors. Certainly at the present time Clemens's solution of the arsenite of bromine, dose one-tenth to one twenty-fourth of a grain three times a day, was the most popular empirical remedy.

It often happens that the complications needed attention and so cod-liver oil for the pulmonary disorders, tincture of the muriate of iron for the failing renal power, Fowler's solution for the pruritus and eczema, digitalis and alcoholics and diffusible stimulants for heart failure had to be recognized as important factors in the treatment.

Dr. Satterthwaite remarked, in closing, that these views were not based merely upon the experiences of writers upon this subject but upon a certain amount of personal observation. He believed, however, that few, if any, physicians could speak from a very extensive experience in the treatment of glycosuria, as it was unquestionably a comparatively rare disease. Of the first ten thousand cases treated at the New York Post-graduate School and Hospital there were but three diabetics, and these statistics tallied exactly with those of Romberg at the Vienna Polyclinic. He had, however, collected forty-one cases occurring in his own practice and in those of his friends, and had used the data thus furnished in reaching his conclusions.

Dr. BACHE McF. EMMET said that he had the records of only two cases of this trouble and both of them had had only the temporary variety. They seemed to be in a debilitated condition and the principal plan of treatment was directed to this. He considered the disease dependent upon an affection of the vaso-motor system. In all probability there was at first an excitement of this system, followed by a paresis. He directed his treatment to the overcoming of this exhausted state: tonics and especially strychnia were employed and a cure had been effected in from six to eight weeks. Both of his cases had been in women and were accompanied with certain troublesome symptoms. They had a constant desire to urinate, and suffered from a urethritis, which was probably caused by the irritating character of the urine. There was also a vaginitis accompanied with intolerable itching; the mucous membrane also having a peculiar dry and glistening appearance. This was probably caused by the dribbling of the urine back into the vagina. This condition he had treated by emollients, such as daseed and glycerin, and the symptoms had yielded readily.

Dr. W. O. MOORE said that Rollo in 1798 first called the attention of the profession to eye trouble in diabetes, although Blankaurst in 1688 mentioned a case of blindness from this disease (though subsequently it was found that both diabetes and blindness were due to a tumor of the brain). The affections of the eye in diabetes mellitus were: disturbances of refraction and accommodation, cataract, opacities in the vitreous, retinitis with and without hemorrhages, and atrophy of the optic nerve and retina from cerebral causes.

Disturbances of refraction and accommodation occurred in the progress of the disease when the general muscular tone was impaired, and they were improved by the fitting of convex glasses and by the use of eserine locally, thus restoring the accommodation. They also usually improved without treatment too, when the condition of the patient was improved. The following case seen in 1879 illustrated this point. E. C., aged thirty-two, lawyer, complained of asthenopic symptoms for a few months before coming under treatment. He had

occasional attacks of vertigo, and an examination showed hypermetropia of one twenty-fourth. No diabetes was present at this time, and the cause of the eye trouble was therefore obscure. In 1881 the patient died of diabetes mellitus. Previous to death he had partial loss of sight due to retinal changes (Retinitis glycosuria).

Cataract was the most common of the diabetic disorders and had long been recognized, usually occurring after the disease had made considerable progress in both eyes. Though differing in degree they were more apt to be soft, yet they might be found hard and firm. It occurred according to Roberts once in forty-five diabetics, while Bouchard found it once in thirty-eight.

The prognosis in diabetic cataract was not as good as in the uncomplicated cases, still he recalled two instances in his experience where the operation for the removal had been all that could be hoped for. If projection of light was good he would operate on any case of fully formed diabetic cataract.

The aetiology of cataract in this disease had been much discussed, and in this connection the experiments of Dr. Weir Mitchell, on frogs, were interesting. He produced cataract in these creatures by injecting syrup into them, but the opacity of the lens would again disappear when the frog was soaked in water. To prove that the opacity thus produced in the lens was not due to dessication, he placed ten frogs in long bottles with wide necks and let them remain there for a time: the frogs emaciated and became shrunken, but no opacity in the lens appeared, although Kunde thought that the cataract was due to deprivation of water.

The clinical fact remained that in diabetes insipidus we do not find cataract. It is probable that it was produced by the changes in nutrition due to the abnormal condition of the blood.

Opacities in the vitreous were frequently found in the progress of diabetes, and were merely seen as small hæmorrhages into its substance, which were absorbed slowly and gave rise to great annoyance. He had a case of this character under treatment at the time. Again, we had retinitis glycosuria with and without hæmorrhages. The former variety had been found quite frequently in the latter stages of the disease and had given rise to confusion in diagnosis, as the retinal appearances were similar to those found in Bright's disease. In some of these cases albumen had, and in others it had not, been found.

DR. JOHN L. BAILLY reported the following case: Mrs. L., aged sixty-one, had been in good health until three and one-half years ago. She had always noticed that the least trouble would produce nervous exhaustion and a sensation of exceeding weakness. In July, 1881, she had a fall and struck the inner side of the left arm and axilla against a piece of timber, but there was no laceration of tissue. For six months after this occurrence this arm was paralyzed, and although the sensation was much impaired, it was not entirely absent. She was informed at this time that she had received a severe injury to the nerves of the part and was advised to apply hot water. At the end of the six months she began to gradually regain the use of the paralyzed limb, and at this time she had almost as complete control over

it as she had over one of the other side. Since the accident she had never felt well and all her symptoms seemed to point toward diabetes from the first. She lost flesh and strength, had excessive thirst and craving for all kinds of farinaceous food, had attacks of vertigo, and was constantly constipated. Even talking would produce profuse perspiration. No measurement of the quantity of urine per diem was made at this time, but from the history it probably amounted to about two gallons. Although she was subject to different treatments, she continued to grow weaker, so that when she came under the speaker's notice, three years after the fall, all the symptoms were well-marked. She suffered particularly with a burning sensation in the feet, so that even on the coldest nights of the past winter she had slept with them protruding from the bedclothes, a window in the room being continually open.

She was put upon milk diet, with half a grain of codeia three times, and fifteen grains of citrate of potassium four times, a day. This was continued for some time after the sugar had disappeared from the urine, when she was allowed to eat sparingly of meat, and from time to time a few vegetables were added. At this stage she was given the tincture of iron, but whenever the glycosuria reappeared she was immediately placed upon the same treatment again.

As a thorough analysis of the urine was made nearly every week during the progress of this case the changes were of some interest. July 23, 1884, daily quantity of urine passed in the twenty-four hours, ninety-six ounces; specific gravity, 1.032; sugar, twenty-six and one-half grains to the ounce; pus, and what at that time was considered to be vaginal epithelium, but since the experiments of Dr. Porter<sup>1</sup> were proved to be from the bladder, was very abundant, showing that there was some irritation of that organ.

August 9th, patient far less thirsty, urine reduced to eighty ounces, and the time between the periods of micturition increased from one to eight or ten hours.

August 14th, specific gravity, 1.028; sugar, ten grains to the ounce; pus reduced to about half the quantity present at the last examination; bladder epithelium also less abundant.

August 22d, one month from the first examination, daily quantity sixty-four ounces, specific gravity 1.025, no sugar, pus only six cells to the field, epithelium abundant.

Up to October 7th, one month and a half from the time that the sugar first disappeared, the urine seemed to be perfectly normal in every respect, but there was always considerable bladder epithelium which had undergone a fatty degeneration, a small quantity of pus, and an abundance of uric acid present. The urine was always strongly acid. About this time casts made their appearance for the first time since the patient had been under observation. They were very abundant and of the small variety, some hyaline, some epithelial, some finely granular, and some fatty. Specific gravity 1.022.

October 18th, specific gravity 1.023, sugar one grain to the ounce, casts abundant, some of the large variety being present, daily quantity of water eighty ounces.

<sup>1</sup> New York Medical Journal, January 25, p. 80.

December 4th, daily quantity sixty-four ounces, specific gravity 1.028, sugar seventeen grains to the ounce, very few casts of the small finely granular variety.

From October 18th to the date of the meeting, nearly two months, there was no sugar, but a great number of casts of all varieties, except the tubular and blood, were represented.

December 25th, daily quantity ninety-six ounces, specific gravity 1.034, sugar nineteen grains to the ounce, casts not abundant but of nearly every variety except tubular and blood.

January 10, 1885, specific gravity 1.026, sugar two grains to the ounce, casts more abundant and still of great variety. No albumen was present at any time. Whenever the sugar was abundant the casts were few and *vice versa*. No great reliance was paid to the daily quantity of urine because it was realized that it was impossible to determine this in females. The patient improved rapidly under the treatment but anxiety and excitement always increased the quantity of the sugar. She felt much better when the sugar was not present, so much so, in fact, that she was able to tell when the glycosuria reappeared.

The following points in this case were worthy of notice: It seemed probable that the injury was the determining cause of the diabetes, but as there was no direct communication between the nerves injured and the nervous mechanism of the liver, it closely resembled the experimental diabetes of Schiff,<sup>2</sup> which was produced by the division of the sciatic nerve. In both instances there was probably super-nutrition of the portal blood as a preëxisting condition. The long-continued nervous irritability may have weakened the nervous system and contributed in a measure to the production of the disease. In responding so perfectly to treatment the case sustained the theory that the overcharging of the portal blood and a hepatic lesion existed prior to the other conditions. The necessity for overcharging the portal blood with hydro-carbonaceous materials when diabetes was experimentally produced by the injury of the diabetic centres argued in favor of an overnutritious condition of the portal system, and a hepatic lesion prior to the nerve injury. The large amount of uric acid contained in the urine was also another proof of an incomplete hepatic metabolism. This case also showed that diabetes was often complicated in its later stages; in fact, that it leads directly to the degenerative catarrhal condition of the urinary tract which was due to the sugar, since improvement was invariably rapid when the sugar disappeared. The ready response to treatment indicated the possibility of a cure when the case was taken in hand early.

Dr. SATTERTHWAITE, in answer to a question, said that in putting a patient upon anti-diabetic diet, much discretion should be exercised, for abrupt and complete exclusion of accustomed articles of food would naturally occasion such a longing for just such articles, that even strong-minded and well-intentioned persons would, at some time or other, break through the rules laid down and gorge themselves with sugary or starchy food to their hearts' content. We should proceed gently, forbidding

sugar first, and then, as the individual had trained himself to subdue the desire for it, throw the starchy foods over one by one. Neglect to observe these principles in the management of a case would often cause failure at the very outset. After sugar had been constantly absent from the urine for two or three months, a gradual but slow return might be made to the ordinary diet. The speaker had found that, as a rule, diabetics did not bear the bran and gluten breads well; some, in fact, refused them absolutely. In his experience, the diabetic bread made by the Health Food Company was unpalatable. But it was certainly possible for the patients to live on a purely nitrogenous regimen, as was abundantly proved by the fact that the Eskimo and residents in the northern hemisphere did so. Symptomatic treatment was next in order after the restricted diet, and the first indications were usually administration of sedatives to relieve the neuralgic and muscular pains. Besides bromides and opiates, valerian and strychnia were the principal remedies used. There appeared to be little danger of contracting the opium habit, if codeia was selected, nor was the usual constipation of the disease greatly aggravated, as the dosage required was not large. For the palpitation, digitalis and alcoholic and diffusible stimulants were often advantageously employed. In the case of a lady under the care of a medical gentleman in his vicinity the green tincture of the *Coreus Boplandii*, in ten-minim doses, was effectually used to control the palpitation that was annoying at night. One dose at bedtime secured the desired result. The speaker was glad to hear of Dr. Emmet's success, as he himself had met with a case in which the disease had been arrested and also knew of another among his personal acquaintances. Of the forty cases he had collected in New York and vicinity, two or five per cent. seemed to have been cured, two or five per cent. had successfully resisted the disease, but of the remainder most were known to have gone on from bad to worse. There was a fair possibility, however, that the percentage of cure or arrest might be found at some time to be better than appeared from these statistics. Many of the patients had passed from observation and, therefore, no deductions could be drawn from them. One case in the second category was noteworthy. The patient had come to him three years before, showing marked emaciation and more obvious symptoms of the disease. He was syphilitic. After an attack of cerebral syphilis he was put upon a six months' course with the result that the diabetic symptoms of his disorder were reduced to a minimum; even now, though he had gained flesh and color, and was in the full swing of an active life, and had little thirst, he felt the need of two bottles of claret for his dinner. Ergotine was used in the second case, in which the disease was arrested, and in combination with the sulphide of calcium and codeia. One grain of ergotine was given three times a day and the codeia in moderate and ordinary doses. One point ought to be insisted upon by the practitioner in assuming the care of a case, and that is that the urine should be examined quantitatively every week to determine the quantity of sugar, so that the results of the treatment might be noted, and, at the same time, a careful examination for casts should

<sup>2</sup> Untersuchung Zuckerbildung In der Leber, 1859

be made, since one of the greatest dangers in this disease was that with the cessation of the sugar and the apparently favorable turn of affairs the more insidious and dangerous nephritic complications might supervene.

DR. A. H. SMITH thought that the theory of the hepatic origin of the disease was not sufficient to account for all the cases; for instance, in those cases which were induced by cerebral traumatism, tumor, mental excitement, as in the case of the duelist in whom diabetes was established after an encounter, where, having delivered his shot, he was obliged to wait for some seconds for that of his adversary whose pistol had missed fire. Those cases where it had followed upon the loss of property and other such severe mental strains might be included in this category. It seemed more probable that the principal seat of trouble was in the nervous system and more particularly in the brain itself. The liver was probably implicated, but he believed that there was a primary lesion back of it. We could not overlook the experiments of Bernard, who found that upon puncturing the floor of the fourth ventricle sugar appeared in the urine without any increase in the amount of the water, but the puncture being made lower down the sugar again appeared, this time, however, with an increase in the quantity of urine, but when the puncture was made on a higher plane the water was increased without the least suspicion of the sugar elements. The sympathetic system was probably the channel for the diseased impulses which were conveyed from the brain or cord, for if the cord were divided above the third cervical ganglion no such result followed from a puncture of the floor of the ventricle, while, if the division were made below this ganglion, the usual results would be noted. It seemed probable, therefore, that the track of the diabetic impulse switched off into the sympathetic system in the region of the third cervical ganglion and through it to the liver. The dilated capillaries of the liver also favored this view, as the nerves that preserved the arterial tone were known to have their origin in the floor of the fourth ventricle. The speaker found a variety of lesions in the liver and considered these, as well as those of the other organs, as probably due to the derangement of the circulation of the blood. The enlarged kidney was unquestionably due to hyperemia, probably from the irritation of the sugar. The low temperature in this condition usually bore a direct relation to the amount of the sugar eliminated, and often fell two, three, or more degrees below the normal.

The extreme fatality of erysipelas occurring in the course of the disease had not been remarked. Facial erysipelas occurring under these circumstances was nearly always fatal. He considered that iodoform fell in the same class as opium and cocaine in the treatment of the disease as its effect was directed toward the nervous system. Several years ago he had treated a patient on the theory that the difficulty depended upon some local irritation of the olivary bodies or about the medulla, and had applied a permanent issue at the bottom of the neck. It seemed to have a decided effect, lessening the amount of the sugar passed, and the patient improved so much without dieting that he was

enabled to resume his duties as a chaplain in the army. He died subsequently, however, of diabetes. The doctor thought that ergot might be of some service in controlling the vaso-motor nerves.

DR. C. H. BROWN used, principally, ergot and bromide of sodium in the treatment of the affection under consideration. He had had two cases in his private practice, and in each he had found the history of a severe mental strain, while a marked symptom in both was the insomnia. Relief followed the treatment in both cases, one recovering at the end of a few months, the other in the course of a year. The bromide was given in doses increasing from twenty to forty grains three times a day. One of these cases, a minister, was of a very sympathetic disposition, allowed his work to worry him, and had more or less family trouble, although he was now apparently quite well, and continued to take the bromides.

DR. LLOYD had had occasion during the past winter to make a number of chemical examinations of diabetic urine, and had at first made use of Trommer's test. But after a series of experiments he had noticed that, when no precipitate had occurred during the boiling, one of a flocculent white character would be deposited during the cooling, if the specimen under consideration contained but little sugar, but an excess of urates or phosphates. This fact led him to institute a number of experiments to determine the accuracy of the test in question. Samples of urine were prepared which contained urates, phosphates, or sugar only, and each was submitted to the test as usually directed in the works on the Examination of the Urine: namely, a small quantity of urine was poured into a test tube, and then a drop or two of the cuppie-sulphate solution and an excess of the caustic-soda or potash solution was added. The result was the same with the specimens containing the phosphates and the urates, but with the sugar solution the characteristic color was observed. Solutions were then prepared which contained large quantities of the other two ingredients, but very little sugar, and then it was found that the color imparted to the supernatant fluid by this one substance was sufficient to apparently color the whole precipitate, and lead to the erroneous conclusion that all the heavy deposit was due to saccharine materials, and that the patient must necessarily be well advanced in the disease. After continuing these experiments for some time the conclusion was reached that if this test was used the phosphates should be first precipitated by heat, and then filtered out, and the urates neutralized by adding the caustic-soda solution before the copper. But when these precautions were carried out the test occupied as much time, and was quite as troublesome as Fehling's, and even then it did not offer as many advantages. He had been forced to the conclusion that the only sure and quick test for glucose, whether quantitative or qualitative, was by the Fehling method, but he could not appreciate the necessity of having it complicated by the three bottles. He had two solutions prepared, and had never found any difficulty in keeping them if the bottles were kept properly corked and care was taken to prevent extraneous material from being carried into them by the pipette. In his experience

Squibb's two-bottle solution was very convenient and accurate.

#### COMPOUND DISLOCATION OF THE FEMUR.

DR. H. M. GUILD, of Vermont, reported a case of compound dislocation of the femur backward upon the calf of the leg. The patient caught his foot in the wheel of a carriage, and when the doctor reached him the limb was shortened about six inches and there was a wound in the sulcus poplitei which was six and one-half inches in length. Through this opening in the soft parts the condyloid extremity of the femur had protruded but no fracture could be made out. The dislocation was reduced and the wound sewed up when the motions of the joint were perfect. The after treatment consisted simply in keeping the limb in a straight position with complete rest, by means of anterior and lateral supports and moderate extension. The wound was treated antiseptically. Although the patient had several attacks of synovitis, his recovery was fairly rapid, leaving him with complete ankylosis, and in less than one year from the time of the injury he was doing considerable manual labor and was now able to go about without the aid of either crutch or cane.

They may last a few hours, and then disappear as suddenly as they came, returning usually in other spots after an absence of a few months or years. They sometimes are situated deeply in the soft tissues or bones of the extremities; at other times they are not localized, but present all the appearances of ordinary neuralgia, and again in some cases the pains are entirely absent.

The condition of the reflexes constitutes the most valuable aids to diagnosis in this disease.

The patellar tendon-reflex is diminished or lost; there may be exceptional cases where the normal knee-jerk is present, but the writer has never as yet observed this, and thought in such cases the sclerosis must have commenced above the lumbar enlargement. This reflex is probably absent in two per cent. of healthy persons. We must therefore know that the person under examination once possessed a normal knee-jerk to enable us to draw any pathological significance from its absence; and the ordinary method of eliciting contracture of the quadriceps femoris, by tapping the ligamentum patellae when one knee is crossed on the other, is not sufficient.

The reflex being absent, the next question to establish is the integrity of the muscular structure of the quadriceps femoris, which can be determined with electricity and mechanical stimulation. If the muscle has a normal response to faradization, or responds by contraction to a tap over its surface, the muscle is healthy and the sign is diagnostic.

Regarding the pupillary reflex, this is diminished or lost. The iris may contract equally, or one pupil be dilated or normal and the other contracted; but the loss of reflex action to the stimulus of light and the absence of response of the pupil to stimulus applied to the surface of the neck accompanied by a normal accommodation is the most striking symptom. The pupil will dilate in a strong effort at distant vision and contract in a powerful effort at close vision. Another common ocular disturbance is temporary double vision; this may last only a few hours, disappear and return in a few months, or it may continue a few days, and not again appear; color-blindness is also very frequent, the ability to distinguish red and green being first lost.

The vesical reflex at the beginning of the preataxic stage is variable; usually the bladder is irritable, but this soon gives place to diminished reflex acuteness, so that there may be no demand to empty the bladder oftener than twice in twenty-four hours. This condition is accompanied by diminished muscular tone of the bladder-walls, so that there is difficulty experienced in starting the act, and the stream, instead of being projected forcibly forward, falls abruptly or simply dribbles, and the patient is often unable to determine when the act is finished and must use his eyes to determine it.

The sexual condition of the preataxic stage is first one of irritability, but is soon replaced by a diminution of all desire and capacity for intercourse, which may in turn be followed by nocturnal emissions.

Gastric disturbance in the preataxic stage is manifested by attacks of violent nausea, persistent vomiting, and pain. The writer cited a case he has under observation where gastric trouble has been

#### CHICAGO MEDICAL SOCIETY.

LISTON H. MONTGOMERY, M.D., SECRETARY.

MEETING March 16, 1885. DR. CURTIS T. FENN, second Vice-President, in the chair.

DR. D. R. BROWER read a paper on

#### LOCOMOTOR ATAXIA: ITS DIAGNOSIS AND TREATMENT IN THE PREATAXIC STAGE.

The preataxic stage, although easily recognized, is usually overlooked, as the result of hasty diagnosis, during which the disease is curable if appropriate treatment of this condition is instituted, but the patient gradually drifts into the second, or ataxic, stage, when derangement of the nervous system is so manifest that a mistake in the diagnosis is then hardly possible, for he falls into the hands of a specialist in diseases of the nervous system, only to be told that he is beyond the possibility of a cure.

The elements entering into the diagnosis of the preataxic stage therefore are of momentous importance, and are: first, sensory disturbances, lighting pains; second, disturbances in patellar tendon-reflex; third, disturbances in pupillary reflex; fourth, disturbances in vesical reflex; fifth, disturbances in sexual condition; sixth, disturbances in gastric function; seventh, disturbances in mental action; eighth, disturbances in muscular function. The first three are the most valuable diagnostic points.

In referring to the sensory disturbances, such as pains of a peculiar character, spots of hyperesthesia and anesthesia in the lower extremities that are sudden, severe, and transitory were dwelt upon; the former are like electric shocks, violent blows, stabbing with knives, or burning with hot irons, compelling on the part of the strongest man violent outbursts of emotional disturbance. The pains are often localized in spots upon the surface that a silver dollar will cover.

the only prominent symptom for five years. The patient during all this time has been treated for a variety of gastric derangements. The attacks recur at intervals, varying from a few weeks to a few months; the patient also has dilated pupils, with loss of patellar tendon-reflex, and occasionally has attacks of lightning pains.

The mental condition is usually altered in the preataxic stage. The patient has fits of melancholy; he becomes morose, irritable, timid, very emotional; will shed tears on the least provocation; loses for a time his interest in business and, to a certain extent, his usual ability in business transactions.

The muscular system in this stage is weak. There is no ataxia, but there is a sense of weight and weariness in the limbs, with difficulty in going upstairs. The condition is quite like that experienced in neurasthenia.

The foundation for the successful treatment of the preataxic stage of this disease is *rest*, absolute, positive, and prolonged. The recumbent posture should be maintained for several months. This plan of treatment is an *innovation*, but is based upon the scientific fact, generally recognized, that a diseased organ should have its functional activity reduced to a minimum quantity. Hence this principle applies with equal force to the spinal cord; for rest, accompanied as it is with diminution of nutriment, activity of nerve fibres, and diminution in the calibre of the bloodvessels, must be antagonistic to the pathological process that has begun. It is, however, necessary to maintain (as Dr. Weir Mitchell has taught us in his treatment of hysteria) the greatest activity of general nutrition, and prevent wasting of the muscles. The judicious use of massage and passive movements will enable a case of locomotor ataxia to replenish the nervous system in the recumbent posture. The diet should be of the most nutritious character; cod-liver oil and the syrup of the hypophosphites are often of great service. The condition of the emunctories should also be constantly attended to.

Electricity, in the form of the galvanic current of mild intensity, used, after the method of general galvanization, daily, is of service, and will, by its alterative and tonic properties, assist in modifying the pathological process. The electrode applied to the spine should be large. The electric brush, with the Faradic current, to the back and lower extremities will by reflex action assist in breaking up the morbid condition, as well as maintain a more healthful condition of the parts during the treatment of rest. Syphilis is probably the foundation of most cases of locomotor ataxia, the reader quoting from authors who had positive evidence of the power of this factor in developing this disease. In his experience of the cases that came under his observation he was sure the treatment of the primary and secondary symptoms of that disease was not energetic or sufficiently long continued.

To guard against the danger of locomotor ataxia mercury and iodide of potassium should be used boldly, and their use should be continued at least two years after the development of the primary sore of syphilis. If development of the disease has begun, then antiphlogistic remedies must be used;

mercury should be pushed to a point short of salivation, and the iodide of potassium given in drachm doses three times a day, or in larger amounts if it can be tolerated by the patient. Iodide of sodium, while not so efficient a remedy, is often better tolerated. Vichy salt is a desirable correction for these large doses of iodide of potassium and mercury. In cases that are not syphilitic, or do not improve under energetic antiphlogistic treatment, nitrate of silver may be given with advantage in doses from one fourth of a grain to half a grain, combined with some excipient that will not decompose it, and administered before meals. One of the wants of success attending the use of nitrate of silver is due to the difficulty of getting it into the blood without decomposition. The reader had used hypodermically with satisfaction the hyposulphite of silver, and found it to be non-irritating, a grain and a half being used daily until ninety grains have been administered. Another drug of undoubted value is ergot, in fluidrachm doses three or four times daily. Cold bathing at a temperature of 65° F. to 70° F. is also of service, while hot baths are highly injurious. Strychnia should also be avoided. The writer then cited histories of a number of cases wherein he had pursued the above plan of treatment, some of whom recovered entirely from the ataxy; others where lost functions have been regained, except possibly the patellar tendon-reflex. A number of the latter were reported as being so nearly well as to resume work or business.

#### DISCUSSION.

DR. H. GRADLE inquired whether the preataxic symptoms may not be another disease, or whether these symptoms may not really be due to a separate disease? The speaker then recited the first case on record, where Laundolt, in 1875 or 1876, stretched the sciatic nerve, thus curing a patient of locomotor ataxia, who subsequently died of some other disease. Upon examination of the spinal cord, this, with the posterior roots of the zones, were found healthy.

DR. G. C. PAOLI stated that but few cases of stretching of the sciatic nerve for any form of difficulty resulted in recovery or benefit to a patient. His own experience did not accord with the views set forth in the paper, regarding syphilis as being the most frequent cause of the disease.

DR. R. TULLY acknowledged the importance of the preataxic stage. It may extend over a period of thirty years, and it is, therefore, difficult to diagnosticate. In the literature on this subject syphilis is the most frequently mentioned cause of the disease. One of the symptoms not mentioned in the paper is the difficulty a patient has in the preataxic stage of walking backward.

DR. BROWER said that the point which he specially wished to emphasize by his paper was the value of complete and prolonged rest in the treatment of the disease.

#### EMPHYEMA, PARACENTESIS, AND DRAINAGE.

DR. E. F. INGALLS read a paper having this title. After referring to the methods of operating with the aspirator needle, free incision, and sudden evacua-

tion of pus, the exsection of one or more ribs, etc., the reader stated that a large ratio of fatal cases, where the radical operation has been made, is due to the operation itself in some of its forms. This, however, must not be taken as an argument against any operation, for recent statistics show that a much larger percentage of cases do now recover who have been operated upon by better methods than if left to themselves. A good result will more frequently follow an operation that will enable us to empty the cavity slowly and at will, and simultaneously keep the cavity thoroughly disinfected. Aspiration will not meet these requirements completely in many cases, therefore a radical operation for free drainage must be made. Yet it is best to precede a radical operation by aspiration, withdrawing the pus several times, if necessary, in order that dilatation of the lung and contracture of the chest-walls may proceed to such an extent that all the fluid may be removed at one time, without causing a distressing sense of compression of the chest and suffocation. When this has been accomplished a few days should be allowed for the cavity to partially refill. Then the operation for permanent drainage should be made. To secure proper drainage and prevent the loss of drainage-tubes in the pleural cavity, the tubes should be prepared as follows: A piece of the best rubber tubing two feet long, nearly a quarter of an inch in diameter, with a calibre an eighth of an inch, should be selected. This is cut half through near its middle, and when folded the two pieces are fastened together at a point about one and one-half inches from the cut with a silk suture, which is tied on the inside of the perforated tube. This suture keeps the tubes in the same relation to each other, and thus prevents one of the annoyances incident to the use of drainage-tubes that are so fastened.

One portion of the tube should be perforated about half an inch from the cut and the other portion perforated in several places, extending from near the cut three or four inches along that portion which is to hang within the chest. As a matter of convenience the outer ends of the tubes are tied tightly, so that pus will not escape through them while they are being introduced. The length of the tubes should be recorded, so that we may know subsequently just how far they extend into the cavity. The difference in the length of the two tubes enables us to know in which one there are several perforations, a matter of importance in the subsequent treatment. Immediately before the operation an aspirator needle or a hypodermic syringe may be tried again to avoid making an opening when adhesions have bound the pleural surface together, and to insure an entrance into the cavity an incision should be made through the skin about one fourth of an inch long through which a broad flat trocar is plunged into the pleural cavity sufficient to allow the easy passage of the two drainage-tubes, which should then, as quickly as possible, be introduced into the cavity to the required depth; the canula is then, of course, withdrawn and the tubes left *in situ*. By careful manipulation entrance of air will be prevented and the tissues will contract closely about the tubes. A piece of sheet-rubber about three inches square, with two small openings near its centre, is then slipped over the tubes down

to the chest-wall where it will act as a valve to prevent the ingress of air in case the tubes should become loose.

In addition to these precautions, to secure the tubes perfectly a section of the same tubing half an inch long, through which have been tied two loops of strong cord, is slipped over each tube with the aid of a canula; these loops are carried down close to the chest-wall and slipped off on the tubes which they fit so closely that slipping is impossible. Long strips of adhesive plaster are then passed through the loops and around the chest, which thus places the tubes perfectly under our control. Over the whole is placed a bandage, between the folds of which hang the drainage-tubes, which are then opened and long pieces of glass tubing are attached. The pleural sac is then washed out with a two per cent. solution of carbolic acid at 101° F., first through one tube, then through the other, until the cavity is clear. After this procedure the ends of the tubes are folded upon themselves and tied, so that they are hermetically sealed; subsequent cleansings should be made two or three times a day. The physician need not call oftener than two or three times a week after a day or two, to assure himself, if necessary, of any change in the injection to secure speedy obliteration of the cavity. In the meantime the "washing out" the cavity may be done by friends or by the patient. In two weeks' time after the operation one of the tubes may be left open hanging in a bottle, which the patient carries in his pocket. In cases of long standing, in addition to the above method, resection of one or two ribs may ultimately be necessary to cause complete closure of the pleural sac, and the patient's chances are greatly enhanced to recover by adopting the first method. The operation for introduction of drainage-tubes and the other methods just described possess the following advantages:—

- (1) It may be quickly and easily performed without an anesthetic.
- (2) It enables us to partially or completely empty the chest, being governed by the effect it produces upon the patient.
- (3) It is free from one great risk incident to free incision into the chest—death as a result of the sudden evacuation of pus and the free entrance of air.
- (4) Air may be excluded from the cavity for several days if care is used, or at most but a few bubbles may enter if the tubes are opened under water.
- (5) The drainage-tubes are held securely and cannot slip into the chest.
- (6) The opening is closed so snugly as to almost wholly prevent the discharge of pus, except through the tubes, thus enhancing the comfort of the patient.
- (7) As a nurse may readily cleanse the pleural cavity, the subsequent treatment is rendered much simpler and easier than where a free opening has been made.
- (8) In chronic cases where resection of a rib or of portions of several ribs may be necessary, this is the best possible preparation of the patient for the operation.
- (9) Eighty per cent. of the patients operated on in this manner will recover.

## Recent Literature.

*Topographical Anatomy of the Brain.* Vol. III. By JOHN C. DALTON, M.D., Emeritus Professor of Physiology in the College of Physicians and Surgeons of New York. Philadelphia: Lea Brothers, 1885.

The prediction of the coming scarcity of this fine work, with which we closed our notice of the first two volumes, appears likely to be verified even sooner than we had thought. The subscription price of twenty-four dollars seemed considerable, though no more than the value of the book, but we see that the publishers have advanced the retail price to thirty-six. We understand that the plates have been destroyed, it being the desire of the author to limit the distribution of the book. We fully sympathize with him in his objection to have the book rendered common by cheap execution, but it seems to be regretted that a greater number of beautiful copies like the one before us should not be obtainable by those who can appreciate them.

This, the concluding volume, contains the plates of Series C, which represent transverse vertical sections, five millimetres apart, from a little before the corpus callosum to a little beyond the posterior extremities of the lateral ventricles. They are twenty-three in number, and as beautiful as those of the preceding volumes. The text is a series of brief descriptions of each plate, with occasional references to those of the other series. The first plate in front of the corpus callosum shows little that demands description, and the same may be said of the second through the front part of that body. The third strikes the anterior horns of the lateral ventricles. With the fourth we enter a most interesting region. The corpus striatum appears on the outer wall of the ventricle. We see the front of the lenticular ganglion, not yet distinctly separated from it, and further out the claustrum. There is a slight depression in the middle of the section, showing that the cut has just opened the fifth ventricle. The next section shows a great change. The corpus striatum and lenticular nucleus have increased rapidly, and now form large masses of gray matter in the midst of the brain. They are still connected below. In Plate VI. they are still larger. The next plate is a striking one. The corpus striatum is much smaller, and distinctly separated from the lenticular nucleus. Below the latter a bold white band shows the course of a part of the anterior commissure. The next section shows a great part of the anterior crura of the fornix. The corpus striatum is still smaller, the lenticular ganglion shows its three divisions, which are easily recognized, and a little of the optic thalamus comes into view. In Plate IX. the optic thalamus is larger and the before-mentioned ganglia smaller. A very interesting feature is the appearance in the temporal lobe of the surcingle, which is the continuation of the corpus striatum. Dr. Dalton had called attention elsewhere to the fact that the arched shape of this ganglion was not generally recognized, and these sections demonstrate the organ in a most satisfactory manner. These few comments enable the reader to judge how the structure of the brain is made apparent. Let it be remembered, moreover, that the three series of plates supplement one another.

## CROUP AND DIPHTHERIA.

ATTENTION has again been directed to the question of the relations of croup and diphtheria to each other by Professor Virchow in a recent address before the Berlin Medical Society, in which this distinguished authority reiterates the views he advocated many years ago, and maintains the different and entirely independent nature of the two affections, so far, at least, as the anatomical seat and pathological lesions of each disorder are concerned.

The term "croup" was applied by Rokitsansky to all affections of the mucous surfaces of the entire body which were accompanied by the exudation of a so-called "false membrane." The fact that certain forms of pneumonia were also associated with a fibrinous exudation gave rise to the name "croupous pneumonia," which has become a fixed term in medicine. The "croup" was originally applied by the Scotch only to acute affections of the larynx, characterized by imminent danger of suffocation from obstruction of the air-passages. Early in this century it was taught that croup of the larynx was a disorder the essential characteristic of which was the exudation of a coagulable material upon the mucous membrane.

As long ago as 1847 the superficial diseases of mucous membranes were divided into three general classes: the catarrhal, the croupous, and the diphtheritic. Diphtheria was then defined as "a process accompanied by mortification (necrosis), having its seat in the substance of the tissue, not necessarily accompanied by the formation of a false membrane on the surface, but in which, if a membrane be present or be exfoliated, an actual loss of substance results in the original membranous tissues at the seat of detachment always leaving superficial ulcerations." The affection is first seated upon the surface of the affected membrane, and the subsequent features of the disease are produced by the invasion of the deeper tissues by morbid elements from the surface. This constitutes the essential definition of contagion.

In distinction to this process we often observe actual fibrinous exudations, which simply lie upon the surface. These are properly called "pseudo-membranes," and may be quite extensive, and are loosely united with the surface of the trachea or larynx, and when, from any cause, they are removed, there is absolutely nothing to be seen upon the exposed surface which can be called an ulceration. These, Virchow holds, are evidently two entirely distinct processes. Varying and mixed forms of both diseases he recognizes, but thinks there is no ground for the assertion so frequently made that all cases of fibrinous laryngitis or tracheitis are due to a diphtheritic infection. Fibrinous exudations in the larynx and trachea may be produced by many causes, particularly by the action of irritants, and these traumatic exudations correspond exactly to those of croup.

The form of pneumonia from which many children die after the subsidence of croup is not in the majority of cases a fibrinous process at all; it is not a "croupous" pneumonia, but is a bronchopneumonia. "Croupous pneumonia," so called, is never actually accompanied by croup of the larynx or trachea. There is no excuse in our day for this term as the definition of a disease of the lungs.

Pneumonia always presents as one of its indispensable features a stage of hæmorrhagic infiltration, while the formation of a croupous deposit is never accompanied by any hæmorrhagic tendency. The term "fibrinous pneumonia" may be applied to this condition for the same reason that the terms fibrinous laryngitis or tracheitis are employed, not to designate an identity or even a similarity of the diseases producing the fibrinous exudation, but to indicate that the products of both diseases present a certain resemblance.

A class of diseases doubtless exists in which we may find both diphtheritic and exudative processes existing simultaneously in the same individual. The diphtheritic process may be present in a mucous surface without membranous exudation, and may often extend into neighboring tissues and organs, as is unfortunately so often observed in the genital passages in puerperal women, and there may be no exudation of laryngeal or faucial or other pseudo-membranes. In these cases the diphtheritic infection is often followed by fatal peritonitis, but no one dreams of considering the diphtheritic process and the peritonitis as one and the same disease, or as due to a similar cause. They are plainly distinct, although interdependent diseases.

The clinical distinction between croup and diphtheria is especially important in relation to prognosis. Simple fibrinous exudations in the air-passages are dangerous, chiefly from the obstruction which they cause. In croup the removal of the obstructing exudation reveals an uninjured and smooth membrane beneath. The exfoliation of the

infiltrated and necrosed masses in diphtheria leaves an ulcerating surface, which must heal by subsequent processes of repair, and may be followed by further dangers to the individual from encroachment of the disease upon important structures, arteries, nerves, etc., as well as from the special accidents consequent upon an open wound upon the affected surface.

It is interesting to note the entire coincidence of the views — of which the preceding is a brief *résumé* — now expressed by Professor Virchow with those uttered by him many years ago. At that period little was known of that great field of bacterial infection or of mycology in any form in which many clinicians and pathologists have been so busily laboring in recent years. Virchow states that the same microscopic bodies were then observed in diphtheria, but they were considered to be a granular fibrinous infiltration of the tissues. Even now there is a great deal of confusion as to the rôle which the organisms found in diphtheria play in the causation of the disease, some authorities claiming that they are simply carriers of contagion or of certain ferments which they have absorbed. In a recent work on Diphtheria Prof. A. Jacobi considers that the intensity of the inflammatory reaction is not dependent on the coæcus formation as such, but on whether the elements it brings with it are deleterious or not. Diphtheria differs from many of the infectious diseases in the lack of protection afforded by one attack against a recurrence of the same disease. It even seems have a special tendency to recur in some of those who have survived the first attack.

Oertel, Nassioff, Eberth, Klebs, and Orth, as well as many others, have observed the organisms belonging to the diphtheritic process in experiments by inoculation with diphtheritic material in the lower animals. Jacobi describes three manifestations of the diphtheritic process: (1) With a membrane lying on the mucous surface, and removable without causing much injury to the epithelium and none to the deeper structures. This seems to correspond to Virchow's "fibrinous exudation." (2) A membrane implicating the epithelium and the upper layers of the mucous membrane. (3) A whitish or grayish infiltration of the surface and the deeper tissues which may give rise to a necrotic destruction of the tissue. The second and third varieties here mentioned correspond to Virchow's diphtheritic exudation.

In distinction to these views is that of Gerhardt,<sup>1</sup> who states: "The difference between laryngeal diphtheria and croup, after having been so much emphasized, cannot be sustained any longer."

A review of the studies in the experimental production of diphtheria would require no little time and space, but we may mention the labors of Drs.

<sup>1</sup> Lehrb. d. Kinderkrankheiten, iv., 1880.

H. C. Wood and H. F. Formad, which were made under the auspices of the National Board of Health, and published in the supplement to No. 7 of the *Bulletin of the National Board of Health* for 1880. These researches led them to the conclusion that no distinction exists between the local appearances produced by diphtheria and those of other pseudo-membranous diseases of the air-passages. Inoculation with diphtheritic material was frequently followed by tuberculosis, while the occurrence of actual diphtheria from inoculation was very rare. The frequency of tuberculosis corresponds to earlier experiments of the late Professor Cohnheim, who, at one time, believed that many indifferent substances were capable of inducing this disease. Later experiments by the same distinguished investigator led to the conclusion that the tuberculosis was due to the use of accidentally contaminated material. It is possible that some unobserved defect in the experiments just mentioned may have contributed to the excessive development of tuberculosis. Our knowledge of diphtheria, however, has not been materially advanced by these investigations.

The recent utterances of Professor Virchow have directed fresh attention to the subject of diphtheria complicated with croup, and it would be well if the question of identity might be at length definitely determined. The difference between the appearances of the diseases as viewed by the pathologist, and the clinical symptoms noticed during life, will doubtless continue to exist, but a more rational mode of clinical study, and especially of treatment, would certainly follow if the true characters and relations of the two affections were firmly established.

#### A DEMONSTRATION AGAINST VACCINATION.

The anti-vaccination sentiment in England has, as it were, precipitated itself in the town of Leicester, where, for a number of years past, there has been an increasing laxness in complying with the provisions of the law. The results obtained by Dr. Cory in his well-known experiment upon the possibility of inoculating with syphilis in vaccinating from an infected child, when care was taken to exclude the use of anything but lymph, seem to have been given special publicity in Leicester, and the opposition to compulsory vaccination of some men high in municipal influence was of great weight in moulding public opinion.

Though it was known that a considerable portion of the growing children had not been vaccinated, yet, in the year 1884, only seven summonses were issued for this dereliction. But, as it became evident that the heresy was spreading, and that at no distant date an epidemic of variola was likely to visit the town, which would find a most favorable nidus for its development, whence it would, in all probability, invade the adjacent country and towns, more

active measures have been taken the present year, and it is said that over 5,000 persons are being proceeded against for neglecting to comply with the law.

But, as so often happens, the recalcitrants raise the cry of persecution, and the rôle of martyr becomes a very popular one. The opposition took form recently in a demonstration which is said to have been attended by 20,000 people. Nor, unfortunately, was it simply a common mob. The mayor of the city received the procession, and a member of the municipal council presided. An effigy of Jenner was hung from a gallows and given the "long drop" at intervals as the procession advanced. Those men who had suffered the extreme penalty of imprisonment made a prominent figure, and others, whose goods had been seized, displayed samples of the otherwise rather commonplace utensils to admiring eyes. The obnoxious parliamentary acts were enthusiastically burned. A wagon carrying unvaccinated children bore the motto: "They that are whole need not a physician."

One cannot help feeling that whenever the remarkable immunity which Leicester is said to have enjoyed for some eight years from this dread disease shall be broken, it may be necessary to finish the above quotation no longer in the words of the original, but sadly to admit that "they that are sick" are beyond the help of any physician.

The corporation having thrown over vaccination are disposed to place their whole confidence upon prompt notification and isolation of every case that occurs. How far these very desirable measures can be made effective against an epidemic of small-pox is a question of much interest, and if the corporation of Leicester could settle it by an experiment which would imperil no lives but their own, many persons would be willing to let them do it. *Fiat experimentum*, etc. But the agitators themselves will not be the chief sufferers. Most of them bear upon their arms the signs of the immunity they will enjoy. It is the unprotected children upon whom the scourge will fall heaviest, and the surrounding country will suffer from any epidemic, and will not have the facilities for "stamping out" the earliest cases that are possessed by an active urban sanitary board. Since scriptural quotations are in order among those gentlemen who are proposing to rely upon sanitary inspection as their only weapon to ward off the disease, we are moved to say: "These things ought ye to have done and not to have left the other undone."

At a time when the scientific mind is hopefully striving after the additional protection of inoculation with attenuated virus against other infectious diseases, this reactionary rejection of the blessings already secured to mankind by vaccination is a grotesque exhibition of the occasional epidemics of

folly which invade communities, and against which a considerable degree of general enlightenment and education seems to be an insufficient prophylactic.

We hope that the remonstrances of a portion at least of the disaffected at Leicester are inspired by an ill-regulated love of liberty, rather than by a stupid hatred of vaccination.

### CHOLERA WARNINGS.

CHOLERA, as since last year there was every reason to expect would be the case upon the approach of milder weather, seems to be cropping up again in more than one part of Europe. The latest reports come from Spain, and, if true, are by no means encouraging. Simultaneously with these rumors of renewed activity of cholera come political complications which indicate that a great Indo-European war may be imminent, a war necessitating the constant transportation to and fro between Asia and Europe, by the Mediterranean and overland, of great bodies of men and vast quantities of material.

Should the possible — many would say the probable — come to pass, all the most favorable conditions for the activity and spread of such a pestilence as cholera may easily be realized this summer. Fortunately our natural position in this country removes us from the ravages of war, and vigilance combined with intelligent forethought may largely mitigate for us the dangers and disasters of disease.

We are glad to observe that our State and municipal Health Boards, as the season advances, are renewing their alertness, especially as under the existing position of sanitary organization at Washington the brunt of responsibility will probably be thrown on them. The Sanitary Council of the Mississippi Valley, representing at its recent meeting at New Orleans, in March, the health organizations and commercial and transportation interests of twelve of the Valley States, showed itself alive to the importance of the emergency. In Illinois the State Board has since last July been making a careful sanitary survey and inspection of the State. Particular attention is being given to the sanitary condition of public buildings, of public institutions, and the railroads have been effectually exhorted to put their rolling-stock and station-houses in wholesome order.

We have just received a timely circular from the Health Officer of the Massachusetts Board addressed to the superintendents of railroad and steamboat lines, urging that they immediately take and maintain such precautions as shall prevent infection along the routes under their charge. Health officials are acting wisely and energetically in preparing for contingencies; those whom it is sought to protect must, and we are sure will, coöperate with them. It is scarcely of less moment to transportation companies as corporations than to communities and individuals that epidemics should be averted.

### MEDICAL NOTES.

— A case of alleged maternal impression is recorded by a correspondent of the *British Medical Journal*, March 28, 1885, occurring in a woman, aged forty-two, multipara, whose menstruation stopped in March. During the same month she saw the "Two-headed nightingale," fainted at the sight, and was so affected that three days after she attempted suicide by jumping from a window. In November she expressed to a medical man, who suspected the existence of twins, a hope that they would not be "Siamese." In January she gave birth to a twin monstrosity, the two children being connected from neck to umbilicus. Both were dead.

— Three cases are recorded in *Annales de Derm. et de Syph.* (see also *Lond. Med. Record*, March 16, 1885), where syphilis was communicated to newborn children by the assistant who sucked the wound in the rite of circumcision. The operator was healthy but the assistant had mucous patches in his mouth. The parents were in all cases healthy but the mothers subsequently became infected in the breast from suckling the offspring.

— In the *British Medical Journal*, January, 1885, Mr. A. J. Campbell suggests a most pleasant and soothing method of employing the douche in cases of insomnia. The patient's shoulders having been wrapped in a sheet or blanket, and his ears plugged with cotton-wool, his head is supported over the edge of the bed (a suitable vessel being placed underneath to receive the water), whilst a gentle stream of water from the rose-spout of an ordinary watering-pot is directed over the head and neck. The watering-pot should be held at least eighteen inches above the level of the patient's head, and the douching may be kept up for three or four minutes: the head should then be lightly dried with a towel, and the patient lifted into his ordinary position in bed. As a rule, sleep is produced within a short period.

— Supported by the late decision of the Supreme Court in *Martin vs. Gleason*, the Boston Water Board has issued the following: "Notice is hereby given to all parties discharging polluting substances into Lake Cochituate, Pegan Brook, or any other tributary of Lake Cochituate, to cease immediately from so discharging or from in any way contaminating the water-supply of the city of Boston. Any further expense of litigation may be saved by complying with this notice."

— Dr. Watclet, who, as we lately remarked, has been fined for violating the rule of professional secrecy by writing a letter for the press saying that a certain patient died of cancer, for the sake of refuting some scandalous reports which had been published about him, has sent back to the prefecture of the Seine the customary certificate in which is asked the cause of death of a patient, declining to

fill it up, and accusing the prefect of playing the part of a tempter in trying to obtain from the physician what the latter knows only under the seal of professional secrecy. Whether the official will take the joke kindly or not remains to be seen.

— In a recent discussion at the Académie de Médecine on the depopulation of France, M. Fournier gave some interesting statistics concerning the influence of syphilis on infant-mortality. The mortality from syphilis among new-born infants reaches 28 per cent. If a mother have contracted syphilis a year before the birth of her infant it is sure to die in infancy. M. Fournier has personally observed forty-four instances of women becoming pregnant during an early period of syphilis; only one of the children born lived beyond its infancy. Among 100 syphilitic women there were 208 pregnancies; 60 living children resulted, and 140 dead; consequently the rate of mortality was 71 per cent. These statistics are furnished by notes taken in private practice. Hospital statistics would probably give a higher rate of mortality. Dr. Coffin stated that, at the Lourine hospital, among twenty-eight pregnant women there was only one who had a living child. M. Fournier estimates that, at the St. Louis Hospital, among 148 pregnant women, 125 lost their children in early infancy.

— George Eliot was sufficiently interested in the following advertisement, which appeared in the *Times* of 1852, to copy and send it to her friends, the Brays:—

“TO GENTLEMEN, — A converted medical man, of gentlemanly habits, and fond of Scriptural conversation, wishes to meet with a gentleman of Calvinistic views, thirsty after truth, in want of a daily companion. A little temporal aid will be expected in return. Address VERAX.”

— It is said that 55,000 physicians are needed in European-Russia alone. This country could easily furnish them and without robbing herself either.

— Dr. Bouchardat, Professor of Hygiene at the Paris Faculty of Medicine, has, after a service of nearly forty years, retired, and his name is transferred to the list of Honorary Professors.

#### NEW YORK.

— At a meeting of the Society of Medical Jurisprudence and State Medicine, held April 9th, Dr. S. O. Vanderpool, formerly health physician of the port of New York, read a paper on Asiatic cholera, in which he said that to whatever portion of the world the disease extends, it spreads no faster than it is carried by individuals. The time had come, he said, when immediate action must be taken, and he advised that an inspection of the luggage of all passengers coming to this country should be at once instituted by the government. The inspection, he thought, should be made upon embarkation, as well

as upon arrival, and all soiled clothing thoroughly cleansed, in order to destroy disease-germs. Dr. Raymond, President of the Brooklyn Board of Health, said that every physician was asked almost daily whether cholera would come to this country this year, and that the proper answer to the question was that whatever precautions might be taken to ward off the disease would certainly have good fruit. Those interested in sanitary matters are looking forward to the coming summer with no little anxiety. Drs. John C. Peters and Stephen Smith and others also spoke.

— Mr. John Drake, the lawyer who was shot by Wm. C. Rhineland in June last, has recently died of pneumonia. At the autopsy it was found that the ball with which he had been wounded had become encysted in the head of the humerus, and that fibrous union of the bone had taken place when the compound fracture had occurred. The external wound was perfectly healed.

— A death occurred in Brooklyn, on the eighth of April, from an overdose of atropia, through the carelessness of a druggist, who put 1.50 milligramme of sulphate of atropia into a prescription in which 1.5 milligramme was ordered. An inquest was held April 10th in the case of a child, one month old, who died under suspicious circumstances on the 17th of March, at which it became developed that a druggist of North Third Avenue, in the recently annexed district of the city, had, by mistake, given the mother of the infant some Dover's powders which had been prescribed for another person. Not long after she had administered the first powder the druggist came to her house and told her that he had given her the wrong medicine. He advised her to keep the child awake and give it strong coffee, but asserted that there was nothing dangerous about the powders. The next morning, however, the child was dead; and, as the result of the inquest, the druggist has been held in \$1,000 bail.

— William Donovan, the young man who skated 1,090 miles in the six days' match at the Madison Square Garden in March, thereby becoming the champion roller-skater of the world, died on the tenth of April. While suffering from extreme exhaustion after his remarkable feat he was seized with pneumonia, and the immediate cause of his death was pericarditis. This is the second death already among the contestants who participated in the match.

— Dr. James L. Little, a prominent surgeon of New York, died, April 4th, of peritonitis, in the forty-ninth year of his age. He was born in Brooklyn, and studied medicine under the supervision of the late Dr. Willard Parker, graduating from the College of Physicians and Surgeons in 1860. He then became a member of the surgical house-staff of the New York Hospital for two years, after

which he was appointed surgeon-in-charge of the Park Barracks. In 1863 he was made clinical assistant to his old preceptor, Dr. Parker, and in the following spring delivered a course of lectures on fractures. He afterward became lecturer on operative surgery and surgical dressings at the College of Physicians and Surgeons, attending surgeon to St. Luke's and St. Vincent's Hospitals, and professor of surgery in the University of Vermont and the New York Post-Graduate Medical School. At several times during the late war he offered his services to the government as a volunteer surgeon, and after the second battle of Bull Run he proceeded to Washington, where he was assigned to the charge of the hospital for wounded temporarily erected there. At a subsequent period he served for a time in the field at White House, on the Pamunkey River, Virginia. His contributions to surgical literature were always of a high order of merit, and his skill as an operator was remarkable. He was especially identified with the operation of median lithotomy and the treatment of harelip deformities, and in 1878 he successfully performed simultaneous ligation of the subclavian and carotid arteries for

aneurism. While highly esteemed in the community on account of his surgical attainments and his sterling character, his many genial qualities in private life won him a large circle of devoted friends. Dr. Little was married, in 1858, to Miss Elsie Charlotte, of Newbern, North Carolina, who, with two sons, survives him.

## Miscellany.

### BASILISKS IN DISEASE.

From the report in a daily contemporary of Professor Brewer's late lecture on "Cholera from a layman's point of view," we take the following sentences:—

"The lecturer here exhibited diagrams giving the shapes of various organisms or *basilisks*, to which he referred. . . . A German physician has discovered the cholera organism which is called the cholera *basilisk*, and is the shape of a little sausage slightly bent. . . . Edward Klein contends that the same *basilisks* which are said to be found in cholera victims are also found in other places, but the lecturer did not consider the theory disproved."

### REPORTED MORTALITY FOR THE WEEK ENDING APRIL 4, 1885.

Cities.	Estimated Population.	Reported Deaths In each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 2,461: under five years of age 832; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrheal diseases) 372, lung diseases 491, consumption 374, diphtheria and croup 121, scarlet fever 70, measles 31, diarrheal diseases 37, typhoid fever 36, cerebro-spinal meningitis 22, malarial fevers 21, whooping-cough 14, erysipelas 12, puerperal fever eight. From diarrheal diseases, New York 23, Cincinnati five, Philadelphia three, District of Columbia two, Lowell, Lawrence, and Chelsea one each. From typhoid fever, Philadelphia 13, Baltimore five, New York and District of Columbia three each, St. Louis, Cincinnati, and Lowell one each. From malarial fevers, New York 11, St. Louis three, Baltimore two, Philadelphia, Buffalo, District of Columbia, New Haven, and Fall River one each. From cerebro-spinal meningitis, New York seven, Buffalo four, Boston three, Milwaukee and Fall River two each, St. Louis, Providence, Nashville, and Brockton one each. From whooping-cough, New York eight, Philadelphia, Buffalo, District of Columbia, Providence, New Haven, and Lynn one each. From erysipelas, New York three, Philadelphia and Baltimore two each, Boston, St. Louis, District of Columbia, Milwaukee, and Brockton one each. From puerperal fever, District of Columbia three, New York one.

Cases reported in Boston: measles 60, scarlet fever 43, diphtheria 28, and typhoid fever six.

In 110 cities and towns of Massachusetts, with an estimated population of 1,366,829 (estimated population of the State 1,555,104), the total death-rate for the week was 20.80, against 19.00 and 19.30 for the two preceding weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,906,446, for the week ending March 21st the death-rate was 23.5. Deaths reported 4,018: infants under one year of age 916; acute diseases of the respiratory organs (London) 487, measles 164, whooping-cough 119, scarlet fever 41, fever 37, diphtheria 32, diarrhoea 26, small-pox (London 19, Liverpool, Manchester, Bradford, Sunderland, and Newcastle one each) 24. The death-rates ranged from 14.0 in Derby to 44.1 in Sunderland; Birkenhead 17.4; Birmingham 24.0; Bradford 23.1; Hull 20.4; Leeds 23.6; Leicester 21.5; Liverpool 28.3; London 21.4; Manchester 32.9; Nottingham 20.2; Sheffield 23.6. In Edinburgh 22.5; Glasgow 30.0; Dublin 34.6. For the week ending March 21st in the Swiss cities there were 42 deaths from consumption, lung diseases 18, diarrheal diseases 11, diphtheria and croup nine, small-pox six, measles and typhoid fever each three, whooping-cough one. The death-rates were: at Geneva 21.3; Zurich 30.7; Basle 21.2; Berne 34.9.

The meteorological record for the week ending April 4th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending Saturday, April 4, 1885.	Barom- eter.	Thermometer.			Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MARCH 28, 1885, TO APRIL 10, 1885.

TAYLOR, M. K., major and surgeon. Granted leave of absence for one month, to take effect about April 15th. S. O. 46, Department of Missouri, March 21, 1885.

HALL, WM. R., captain and assistant surgeon. Granted leave of absence for one month and fifteen days, to take effect when his services can be spared. S. O. 70, A. G. O., March 27, 1885.

GARDNER, JNO. DE B. W., captain and assistant surgeon. Ordered for temporary duty at Fort McHenry, Md. S. O. 64, Department of the East, March 28, 1885.

BLAIR, VICTOR, captain and assistant surgeon. Leave of absence extended six months on surgeon's certificate of disability. S. O. 77, A. G. O., April 4, 1885.

CAPT. STAYERS, G. COWDREY, assistant surgeon. From Department of East to Department of Missouri.

CAPT. AUGUSTUS A. DE LOEFFE, assistant surgeon. From Department of East to Department of Dakota.

CAPT. LOUIS W. CRAWFORD, assistant surgeon. From Department of East to Department of Platte.

CAPT. GEORGE H. TORNEY, assistant surgeon. From Department of Missouri to Department of East.

FIRST LIEUT. W. L. AUSTIN, assistant surgeon. From Department of Platte to Department of East.

FIRST LIEUT. M. J. WYCHEL, assistant surgeon. From Department of Dakota to Department of East.

S. O. 77, A. G. O., April 4, 1885.

CARTER, E. C., first lieutenant and assistant surgeon. Granted one month's leave, with permission to apply for one month's extension, to take effect upon the arrival of another medical officer at his post. S. O. 30, Department of Arizona, March 23, 1885.

#### MEETING OF THE AMERICAN MEDICAL ASSOCIATION AT NEW ORLEANS. ROUTES AND RATES FROM BOSTON TO NEW ORLEANS AND RETURN BY NEW YORK AND NEW ENGLAND R. R.

The attention of those intending to go to New Orleans to attend the American Medical Association is directed to the rates and routes of the New York and New England R. R. in the advertising columns.

#### DEATHS.

DIED, in Boston, Mass., April 10, 1885, William Osgood, M.D., M.M.S.S., aged sixty-two years.

In Cambridge, Mass., April 13, 1885, Robert William Hooper, M.D., M.M.S.S., aged seventy-four years.

In Boston, April 13, 1885, Samuel Cabot, M.D., M.M.S.S., aged sixty-nine years.

#### BOOKS AND PAMPHLETS RECEIVED.

Observations upon the apparent Curve of the Sagittal Suture in Vertex Presentations. By Charles F. Willington, M.D. (Reprint from American Journal of Obstetrics, March, 1885.)

On the Use and Abuse of the Pessary. By Walter P. Mantou, M.D. (Reprint from Detroit Lancet, January, 1885.)

Spinalties and their Relation to the Medical Profession. By L. Duquesne Bulkeley, A.M., M.D., New York. (Reprint from Journal of American Medical Association, December 13, 1884.)

State Provision for the Insane. By C. H. Hughes, M.D., St. Louis. (Reprint from Alienist and Neurologist, April, 1885.)

Manual of Diseases of the Ear. For the use of Students and Practitioners of Medicine. By Thomas Barr, M.D. Glasgow: James Macdosh & Sons, 1884.

## Original Articles.

## THE PRINCIPLES OF SANITARY PLUMBING.

BY J. PICKERING PUTNAM, OF BOSTON.

As announced in the invitation cards to this lecture, a number of the appliances used for illustration are inventions of my own, and some of them are patented. These devices have been clearly marked on the drawings with their name, "Sanitas," and in referring to them they will always be so designated. The object of this is that every one may know when anything of my own is referred to, and be able to assure himself that the subject is treated without bias. My intention is to make no statement which is not founded on facts recognized by all or easily demonstrated, nor to follow any course of reasoning which is not perfectly clear and logical. In order, moreover, to make our meeting as satisfactory and fruitful as possible, it is hoped that every one will make a note of any point which may not be perfectly clear to him, or of any deductions with which he may not be fully in accord, and mention them in the discussion following the lecture, so that the reasoning leading to these deductions may be re-examined or more clearly stated.

It is proper to add that the devices are the outgrowth of a careful practical study of plumbing made from the unprejudiced standpoint of the architect working for the interest of his client.

They are the *result*, and not the *cause*, of the investigations.

As plumbing is now practised, the architect or the sanitary engineer is, from the nature of his work, the one upon whom we must depend chiefly for its improvement. Evidently the most important part of an architect's work is that which concerns the health and comfort of his client.

The arrangement of the plumbing, pipes, and fixtures influences the entire plan from foundation to roof.

Some of the rooms, such as the laundry and toilet rooms are designed exclusively for the plumbing, and all are more or less dependent upon its arrangement. The walls and beams must be slotted and framed for its reception, and differently for each different kind of fixture or system of piping and for their lighting and ventilating apparatus. Hence, the architect must be familiar with all the details of the work, and upon him lies the responsibility, not only for the healthfulness, convenience, and cost of the particular work over which he has immediate charge, but also, in a great measure, for the general status of the art of plumbing throughout the country. The plumber, like the architect, may see defects in the methods of plumbing now in vogue, but he has comparatively little interest in promoting reform because the authority lies with the architect. The plumber has contracted to do a certain amount of work for a certain amount of money and it is not easy for him to alter the contract. If he is directed to put into a house a few hundred dollars' worth of piping more than is necessary or desirable, or set complicated

or ill-devised fixtures, it is not his duty to protest. Competition has reduced his profits to so small a figure that the plumber cannot afford to be an active reformer.

The physician seldom interferes in the details of plumbing work, and the public are, as a rule, profoundly ignorant of them.

The architect, however, acting directly as the agent of the owner, is bound, when he discovers defects affecting the health as well as the pocket of his client, to use all the influence he possesses to remove them.

Every sanitarian recognizes the serious defects of our present plumbing methods and apparatus. Our common soil and waste pipes are neither gas nor water tight on account of their defective form and jointing, and they are expensive to lay.

Our traps either are incapable of retaining their water-seal against the adverse influences affecting them in common use, or they are bulky, unscientific, and expensive.

Our lavatories are slow emptying, inconvenient, and complicated. Most of the water-closets in use are full of defects and flushed on incorrect principles, and, in short, there is scarcely a single point in which our plumbing is not evidently susceptible of great improvement.

Let us examine these defects and study the principles which should guide us in effecting their cure:—

*Simplicity.* The tendency at present is toward undue complication. The plumbing work is becoming each year more elaborate and costly, more difficult to set correctly, and more difficult to comprehend and repair when correctly set, so that the public are becoming alarmed and confused. They despair of being able to understand the intricate system of piping and machinery for the supply and waste of fixtures. The result is a general feeling of insecurity and a tendency to forego the convenience of plumbing fixtures wherever their presence is not an absolute necessity.

Our byword should be "simplicity." Rather than reduce the number of our fixtures, let us reduce the amount of machinery connected with them, provided we can do so without diminishing the security they are intended to afford.

If we find that our process of simplification actually increases the security of the work, all will be gainers—the public as well as the plumber. For what is best for the public by increasing their confidence is also best for the plumbers, though they appear now to lose sight of this fact.

*Accessibility.* Another leading principle is that all plumbing work in a house should be everywhere, without exception, accessible and as far as possible visible.

Pipes should never run behind plaster when it is possible to expose them on walls and ceilings. The pipes both waste and supply as well as the bathtub traps of a bathroom should be placed, if possible, on the ceiling underneath the plaster of the bathroom or china-closet below—never between the floor-joists. There is nothing in a neatly arranged line of lead, brass, and iron piping that one needs to be ashamed of. On the contrary when skilfully placed and neatly jointed in a workmanlike manner, as

<sup>1</sup>Read before the Section for Clinical Medicine, Pathology, and Hygiene, of the Suffolk District Medical Society, February 16, 1888.

would be the case when the plumber knew they were to be forever exposed to view, these bright metal pipes become quite ornamental when mounted with lead or brass clamps on strips of finished woodwork varnished and symmetrically arranged in corners or where good taste and judgment direct.

In the darker ages of architectural art, chimneys were despised and hidden from view. Now they become the most prominent features of a design, suggesting hospitable comfort and healthful ventilation within. So should it be with the piping. A knowledge on the part of the house-owner that all the pipes which provide him with the comforts of pure water and safely carry off the foul are in full view and in a sound condition will afford him much solid satisfaction.

*Avoidance of Mechanical Obstructions.* A third principle is to avoid all mechanical obstructions, such as valves, balls, gates, and all other impediments to the water-way, and in a system of water-carriage to do all trapping by means of a water-seal alone.

Mechanical devices form no reliable security against the passage of sewer gas. These valves and balls cannot be made to fit their seats with such accuracy as to exclude liquids and gases, or microscopic disease-germs, even when new. They soon become more or less fouled with dirt and corrosion and then their inefficiency becomes evident even to the eye. A sound water-seal however, properly protected, is found to be entirely reliable in excluding noxious matters of all kinds.

Fig. 1 represents a trap having the undesirable mechanical seal in the form of a ball.

Fig. 1. The Jennings trap, with mechanical seal.

Moreover we are obliged to rely upon a simple water-seal whether we desire to or not, because our water-closet traps or their overflows are, and must be, constructed without mechanical obstructions. Evidently if the water-seal is inefficient we must either construct our water-closet traps and their overflows on a different principle or else give up the system of water-carriage altogether. It is useless to apply mechanical closures to our smaller traps if we leave the large water-closet traps without them.

It has been shown by Dr. Carmichael and others that if a water-seal be properly maintained against evaporation and siphonage, or destruction from any cause, the amount of sewer gas that can pass through in twenty-four hours, even under the worst conditions, but with a ventilated soil-pipe, is infinitesimal and absolutely harmless, and that disease-germs cannot pass at all through water at rest at normal temperatures. Dr. Carmichael also experimented with an unventilated soil-pipe, and found here that the quantity of carbonic-acid gas, the largest component of sewer gas, given off from the traps in twenty-four hours was less than that obtained "when a bottle of lemonade was opened," and less than that which is exhaled by a man in five minutes.

As for the ammonia, sulphuretted hydrogen, and other gases or vapors which accompany the carbonic acid, their combined amount, even under the un-

favorable conditions of a foul sewer and unventilated soil-pipe, was hardly equal to the one thousandth part of that of carbonic acid, and this amount diffused in twenty-four hours through the atmosphere of a house is evidently absolutely insignificant and harmless. With a ventilated soil-pipe the quantity which can pass through the water-seal was found to be about four times less, probably far less than what would come into our city houses through the doors and windows from the ventilating openings in the streets of the public sewers.

Drs. Carmichael, Pumpelly and Smith, Naegeli, Wernich, Miquel, and others, have shown that disease-germs and bacteria generally have the same "mechanical affinity" for water which we observe in all solid particles, particularly of organic nature. They cannot rise spontaneously from the surface of water at rest, and at the normal temperature of our houses. It is only when the surface is violently agitated, or when gaseous bubbles rise to the top and burst, that these particles are released and dissipated in the atmosphere. With a ventilated soil-pipe no such effervescence in the water of a trap can take place, and the agitation of its surface caused by properly arranged flushing does not throw water out of the trap nor allow of the escape of any germs of disease, for any water which may be washed up on the sides of the trap above the normal water-line is quietly carried down again by the upper flushing stream and swept into the sewer.

The experiments of Dr. Carmichael resemble absolute demonstrations and may be accepted as conclusive. He concludes his report as follows: "Water-traps are, therefore, for the purpose for which they are employed, that is, for the exclusion from houses of injurious substances contained in the soil-pipe, perfectly trustworthy. They exclude the soil-pipe atmosphere to such an extent that what escapes through the water is so little in amount and so purified by infiltration as to be perfectly harmless, and they exclude entirely all germs and particles, including, without doubt, the specific germs or contagia of disease, which we have already seen are, so far as known, distinctly particulate."

*Tightness of Joints.* A fourth principle is that all joints should be permanently tight, and to secure this evident desideratum no material should be used in jointing which is injuriously affected by any of the substances brought in contact with them or by movement produced by changes of temperature, concussion, or shrinkage.

*Soundness of Material.* A fifth principle is that all the material used be sound, and all pipes of even thickness and capable of resisting a suitable pressure-test.

*Ventilation.* A sixth principle is that all the main lines of soil and drain pipes be thoroughly ventilated from end to end.

*Flushing.* A seventh principle is that all parts of the waste receptacles and pipes be thoroughly flushed with water from end to end in such a manner as to remove all foul matter instantly from the house as soon as it is generated.

*Automatic Operation.* An eighth principle is that the working of all parts of the plumbing system should be as far as possible automatic.

**Noiselessness.** A ninth principle is that the operation of all parts of the work should be noiseless.

**Economy and Prevention of Water-waste.** Finally, all parts of the work should be economical in construction and designed in such a manner as to avoid the chances of waste of water through leakage.

These ten broad principles are not only accepted by all the leading sanitarians, but are self-evident and may be at once adopted as axioms without discussion. In the manner of applying them in practice, however, we do not find the same universal harmony. Where all are in accord I shall make no reference to authorities. But where there is a difference of opinion among experts I shall call attention to the fact, so that each one present may form an independent judgment of his own.

#### TRAPS.

The first subject we shall consider will be the trap.

Its form depends upon the nature of the work it is called upon to do; the form which is suitable for a water-closet being quite unsuitable for other fixtures.

The agencies which tend to destroy the water-seal and efficiency of traps are: siphonage, evaporation, back pressure, capillary attraction, self-siphonage, leakage, and the accumulation of sediment. These agencies must therefore all be considered in the design of our trap. What form shall we give it to enable it successfully to withstand them?

We find that if we adopt the simplest possible form, that of the S trap, which consists merely of a bend in the pipe deep enough to make a seal, we obtain a device which, with proper flushing, is sufficiently self-cleansing and furnishes the easiest outlet for the water. But it is unable to do any more without external aid, and quickly loses

its seal under the slightest disturbance of atmospheric pressure produced by a sudden flow of water through the pipes with which it is connected.

Three methods have been employed with a view to preventing the destruction of the seal by siphonage.

One is to ventilate each trap by connecting it with a special ventilating pipe constructed for the purpose.

A second is to increase the size of the upcast limb of the trap until it becomes a "pot" or "reservoir" trap large enough to accomplish the same result without external aid.

A third method is to construct the trap in such a manner as to render it both antisiphonic and self-cleansing at the same time.

The first method adds greatly to the cost and complication of the work. It has given rise to the so-called "trap-vent" law, which rigidly requires every trap, under all circumstances, to be ventilated.

In regard to the practical working of trap ventilation two things have been found:—

First, that it is not always efficient in preventing siphonage.

Second, that it is always more or less active in destroying the seal through evaporation.

Nevertheless, this method still has a few advocates of recognized ability. But they now adhere to it chiefly, if not entirely, on account of an alleged indirect advantage produced by the air-current in partially oxidizing foulness in the waste-pipes.

The second method is both inexpensive and simple and is much more efficient in resisting siphonic action than the first. It has, however, the serious disadvantage of involving the use of cess-pools or filth-retainers in the house, and such retention is in violation of a leading principle of sanitary drainage which calls for complete removal of foul matters from the premises the instant they are generated.

This method has however a very large number of advocates who consider the retention of a limited quantity of filth in the trap less of an evil than the dangers of difficulties coming from trap-venting. They claim that a guard which is only *sometimes* reliable is worse than none at all as giving a false sense of security, and that the purification of the branch waste-pipes can be effectually accomplished by powerful water-flushing, making the induction of the air-current for this purpose quite superfluous. They find, moreover, that abundant aëration goes on without the aid of the vent-pipe both from diffusion of the air in the ventilated soil-pipe, and from the powerful influx of air induced with, and after, the water-flushing at each usage of the fixture.

The third method is the simplest and least expensive of all. It is more reliable than either of the others in resisting siphonic action, and does away with the serious objection of the second method: that of filth retention.

It has already the advocacy of many of the leading sanitarians of the country and promises to be universally adopted as soon as it becomes generally known.

Let us now examine these three methods carefully in detail, since the question is not only one of the most important and interesting ones in the whole domain of sanitary plumbing, but its investigation will throw light on every other part of the subject.

**Trap-ventilating.** Until very lately it was supposed that trap ventilation afforded a reliable cure for siphonage, and under that supposition the trap-vent law was made. This law has been in operation but a very few months and in a few large cities, yet it has been in force long enough to show in the first place that it is by no means able to do what it pretends to even when the vent is newly and skillfully applied, and in the second place that it gives rise to new evils as great or greater than those it was intended to obviate, and in the third place that the vent-pipe itself tends to become foul in usage, and that in some cases the accumulation of foulness goes on to such an extent, especially at its point of connection with the trap, as to completely close the air-passage and destroy its operation.

Fig. 2. Ordinary S trap.

We will first test the efficiency of the trap-vent when it is new and clean and afterward consider the question of its partial or complete closure by filth accumulation.

*Tests on Traps Newly Ventilated.* In making these tests two points have been very carefully followed, and these must be distinctly understood.

In the first place the apparatus and arrangement used is precisely the same in character as is found most commonly in the best ordinary practice.

A large number of return bends and a very long stack of piping has been put together in order to permit a variety of different tests to be made with a single compact apparatus. But as openings have been made in the pipe at various points, we are able to cut off one or all of the bends and any part of the length of pipe at will. Hence, the apparatus

Fig. 3. Apparatus used for trap testing.

may be made to correspond with that in any form of house we desire to imitate.

In the second place, though our tests will be very severe, they will, nevertheless, be no more so than is often encountered in practice. Our object is not to show what *usually* takes place but what *at any time may* take place.

We do not of course pretend to say that a new vent-pipe can never protect a trap, but that it cannot always be relied upon, and that this being the case, it affords a false sense of security, and is therefore worse than nothing for we can never tell at what moment it will fail in its duty.

If we are to be forced by the law to put our clients to the great expense and danger of ventilating every trap, we have a right to demand: first, that the means employed shall actually afford us the security it pretends to, and not fail at the first critical

moment, and, second, that no other simpler and better means exist for securing the desired results.

Our apparatus consists of a stack of four-inch soil-pipe with two ordinary plumbing fixtures ten feet above the wastes of the traps to be tested. On the left is a Jennings closet and on the right a Zane: kinds which have been perhaps until lately the most popular in this country.

Fig. 3 represents the apparatus used. The distance from the floor to the upper platform which supports the water-closets is fourteen and a half feet. From the floor to the ceiling is seventeen feet.

It is hardly necessary to explain to the present audience that the smooth bends and returns we have used add but very slightly to the friction.

Smooth bends of a radius equal to, or greater than, the diameter of the pipe are found to have very little effect in retarding the flow of fluids. To show just the effect such bends produce in the present case we have provided openings at different points in the length of the piping and after experimenting with all the bends, we will make other tests without them or with only a portion of them, and compare the results. We have used the ordinary two-inch iron pipe for back ventilation.

Just above the floor of this room we have provided two Y branches for the trap waste-pipes to be tested using ordinary one and a half-inch bath or basin lead waste-pipe of the average length. We find the length of these branches within reasonable limits does not appreciably affect the siphoning action.

*Experiments on a one and a half-inch S trap.* The first test we will make on an ordinary one and a half-inch S trap unventilated. The soil-pipe we leave full length. The seal is two inches deep.

(Discharge of Z and J together.) We see that a single discharge of the two closets has completely destroyed the seal in a second, leaving scarcely a drop of water in the trap.

If we shorten the soil-pipe one half by removing the plug at forty-five feet length, we find substantially the same result. (Discharge of Z and J together.) The seal is again instantly destroyed.

This is the simplest possible illustration of the phenomena of trap siphonage, and so far the result is probably familiar to most of the audience here to-night. All are aware that an unventilated lavatory S trap with even an unusually deep seal possesses scarcely any power to resist siphonage. When the falling water in the soil-pipe produces the partial vacuum behind it as it descends, if the soil-pipe extension above it is short and closed at the top, the action is at its maximum because there is very little air to expand. If the pipe is short and open it is at its minimum. If it is long and closed still the action is powerful, but if it is long and open above, a medium effect is produced, and this is the condition we have to-night in our apparatus.

Let us next see what the effect of a discharge of a single closet will be, leaving the soil-pipe forty-five feet long. This cuts off three bends, leaving it four.

(Discharge of the Z alone.) The Zane closet alone has siphoned out the trap in a single discharge. Let us try the Jennings alone.

(*Discharge of J alone.*) The Jennings alone has also instantly unsealed the trap.

Thus we see that either a Zane or a Jennings plunger-closet is easily able to destroy the seal of an ordinary S trap under the simplest conditions of plumbing. Any other form of plunger-closet or any valve or properly constructed hopper-closet would probably do the same.

Let us now ventilate our trap with a vent-pipe the full size of the bore of the trap. Leaving the soil and vent pipes the full length we will discharge the closets as before.

(*Discharge Z and J.*) The first discharge has reduced the seal from two inches to one and a half inch. It will be observed that our vent-pipe is actually considerably larger than the bore of the pipe which is contracted at the bends, so that the protection afforded by this is greater than it would be in ordinary practice.

Another discharge has lowered the seal to one fourth of an inch. A third discharge has completely destroyed the seal, leaving an open passageway into the house for sewer gas.

(*To be continued.*)

#### A PECULIAR FORM OF URIC-ACID PRECIPITATE.

BY F. W. ELLIS, M.D.

SEVERAL months ago I met with a case in my private practice which presented features sufficiently unusual and interesting to justify a few notes.

I was consulted by a large, well-built Irishman, who complained of various dyspeptic symptoms. His occupation was that of a stonecutter. He complained of muscular weakness and poor appetite. He had been ailing for a considerable time, and had recently returned from a trip to Ireland, where he spent a year in idleness in order to regain his health. He returned home somewhat improved and resumed his trade. He was married and, so far as could be learned, had always been temperate.

I was first consulted by his wife who had noticed a peculiar condition of his water. The specimen of urine which she brought to me for examination was pale and a half-litre or more in amount. The sp. gr. was low (about 1.010), but, as I have lost the record of the examination, I cannot state the exact figure. A relatively large amount of large rhombic uric-acid crystals had collected as a sediment. It was this sediment of large red crystals which had first excited the attention of the patient's wife. After standing a short time a much more abundant chalky, white sediment collected above the red uric acid. This white sediment was insoluble in concentrated hydrochloric acid. A portion of the sediment boiled with a large amount of water slowly dissolved. Under the microscope it was seen to be composed of very minute rectangular prisms. That it was not any form of urate was shown by its insolubility in acids and its very imperfect solubility in boiling water. Treated with nitric acid and ammonia it gave a very beautiful murexide reaction. It dissolved readily in the caustic alkalis, and was reprecipitated by acetic acid in the form of

perfectly colorless rhombic prisms, showing that it was entirely composed of an exceedingly pure form of uric acid. No more uric acid could be separated from the filtered urine. In other respects the urine was normal.

A sample of urine analyzed a few days later contained only a slight amount of uric acid. The increased excretion of the acid seemed to occur in paroxysms. I analyzed several later specimens, all showing enormous increase in the amount of uric-acid sediment, the greater part of which was in the form of a white precipitate of small colorless crystals. The sp. gr. varied; on one occasion it was 1.023. The reaction was strongly acid.

The interesting points in this case are: (1) The enormous increase in the uric-acid sediment occurring in paroxysms. (2) The dual character of the uric-acid sediment, the large red, rhombic crystals, and the very minute colorless prisms. The large red crystals were probably of slow formation; this was shown by their perfect rhombic form. The minute prismatic crystals must have been so suddenly precipitated as to leave no time for the absorption of coloring-matter. The two kinds of crystals must have formed at two different times. The white sediment of pure uric acid might easily have been mistaken for one of urates had the examination been less careful.

I am not aware of a similar urinary sediment having been described in print, and it is doubtless one of some rarity. The patient had no symptoms of stone.

#### DESCRIPTION OF AN EXCISED HIP-JOINT TWENTY-TWO YEARS AFTER THE OPERATION.

BY L. E. WOODWARD, M.D., OF WORCESTER.

THE patient, a woman aged twenty-nine, engaged me for her confinement with her second child, and allowed me to make a careful examination of the left hip-joint, which had been excised for hip disease twenty-two years before. The history of the case is briefly as follows: The disease began at the age of five years, and an abscess formed two years later. Dr. Credarwitz, of Brooklyn, N. Y., excised the head of the femur at this time, the patient then being between seven and eight years old. The sinuses continued to discharge for about three years. Since then she has had no trouble with the hip.

There was a well-formed head to the femur, beneath the scar of the operation, which rotated under the hand. The whole limb was shortened three inches. Two and one-half inches of this shortening was in the thigh and half an inch in the leg. There was a difference of three inches in the circumference of the thighs, of one inch in the calves, and the foot on the affected side was half an inch shorter than its fellow.

All joint-motions were possible. Flexion was nearly equal on the two sides. Extreme extension was impossible, but the popliteal space could be brought down to the bed without tilting the pelvis. External rotation was limited to about two thirds, and internal rotation to about one third, of the normal amount. Abduction was about one half the

normal, while adduction was the least perfect of the motions, there being not more than a fourth as much on the affected side as on the other. The patient has been free from pain since the sinuses healed, and with a high shoe can walk with comfort. She has supported herself by sewing, and runs her sewing-machine with either foot. I was unable to learn just how much of the head of the bone was removed, and it is possible that the trochanter was saved. Vaginal examination showed nothing abnormal in the pelvis, and her labor was easy. The limb in this particular case is much more useful than the ordinary joint of spontaneous recovery.

### REPORT OF PROGRESS IN ORTHOPEDIC SURGERY.

BY E. H. BRADFORD, M.D., AND H. L. ECKRELL, M.D.

#### COMPARATIVE RESULTS OF TREATMENT IN CHRONIC OSTITIS OF THE HIP.

V. P. GIBNEY<sup>1</sup> draws the following conclusions from his large experience in the treatment of this disease: (1) The "expectant" treatment is not, in an orthopedic or surgical sense, any treatment at all. (2) Traction with motion is based upon a false pathology, and does not, in my opinion, do what its advocates claim for it. (3) Fixation and rest, when properly carried out, yield better results, I believe, than any other plan. (4) The keynote of treatment of osteitis of the hip is not the splint employed, not the crutch, nor the high shoe, but it is the management of the case. The case must be closely watched, the apparatus must be fully kept up to its duty, the indications must be met, and one must not grow impatient, because time is an important factor.

#### OPERATIVE INTERFERENCE IN JOINT AFFECTIONS.

Volkman<sup>2</sup> calls attention to the fact that in adults tuberculosis of the knee-joint is, as a rule, primary, and begins in the synovial membrane and rarely extends to the bones and if it does only superficially. In children the reverse is the case. A small deposit of tubercle, varying in size, is to be found in bone, while the cartilage is usually unaffected or nearly so. From these facts he is inclined to consider that the removal of the joint surfaces of bones is not called for in adults and in children removal of the epiphyses may be avoided in most cases.

As a substitute, Volkman advocates a total excision of the affected capsule in fungous disease of the knee, leaving the bones and cartilages untouched except where foci exist, in which case they should be spooned or chiseled out. If deformities are present, they should be first corrected and abscesses should be freely incised as a preparatory measure. The joint is to be partially opened by a transverse incision, and this is to be enlarged if it is found, after digital exploration, that the disease is sufficiently large to justify complete excision of the

capsule and the patella divided by a saw. If the bursa under the quadriceps needs to be removed the incision is to be enlarged so as to lay bare the whole cavity of the synovial membrane and the remnants of the simular cartilages removed with scissors and scalpel until sound tissue is reached. The wound is finally carefully closed with sutures, the divided patella having been united with catgut, and the tendon of the quadriceps or the ligamentum patellæ (if divided) sutured in. Frequent drainage-tubes should be inserted. The operation should be done with frequent irrigation of the large surface with a sublimate solution. The wound heals by first intention except where the drainage-tubes are, and the result is a stiff knee, much firmer than when resection has been done. A firm support is to be worn for a long time to overcome the tendency of the flexors to contract.

Ollier<sup>3</sup> agrees with Volkman's statement of the pathology of these affections, namely, that the disease in adults is chiefly seated in the synovial membrane and in children chiefly in the bone. In children Ollier opens the joint freely, excises and destroys fungosities with the hot iron and scoops out foci. In adults, however, he prefers amputation or resection.

#### SURGICAL TUBERCULOSIS.

Dr. R. J. Hall has contributed a valuable paper on this subject to the New York Surgical Society.<sup>4</sup> In review he states that, as a rule, the bacilli are abundant in tubercular lesions of mucous membranes and internal organs, while they are found very sparingly in those of the skin, bones, and joints; a rule, however, not without exceptions. Two important practical subjects are considered, namely, the means of diagnosis at the command of the surgeon, and the indications for treatment.

"For the first, as a rule, the clinical diagnosis is not difficult. All that we have been accustomed to consider serofulous must be classed as tubercular, with the exception, probably, of those superficial affections of the skin and mucous membranes which are rather diseases of the serofulous than serofulides.

"But far more than this must be included. Its forms are so various, and its course so dissimilar in different cases, that sometimes before operation only a probable diagnosis can be made, and that largely by exclusion. We must be prepared to recognize tubercular lesions of the bones, the joints, the skin, etc., in both children and adults, who, except for this one affection, present all the appearances of the most blooming health."

Dr. Hall fairly puts the status of the bacillus in its relation to surgery. He thinks that, practically, the simple examination of the tissues affords a perfectly reliable and simple means of diagnosis.

As regards treatment, the discovery of bacillus has taught us, when local recurrence takes place after operation, to seek a cause, not in any mysterious predisposition of the tissues to tubercular inflammation, but in the failure completely to remove the infecting material. He considers that

<sup>1</sup> Philadelphia Medical Times, December 13, 1884, p. 190.

<sup>2</sup> Centralblatt für Chirurgie, No. 9, 1884, Allg. Medical News, April 4, 1884, p. 190.

<sup>3</sup> Revue de Chirurgie, No. 3, 1885.

<sup>4</sup> Philadelphia Medical News, January 24, 1885.

are apparently far from obtaining any specific action by internal medication.

He concludes his excellent paper by prophesying with our improved methods of wound dressings an earlier and more frequent radical operation.

#### SPINAL ARTHROPATHIES.

A. Sydney Roberts,<sup>5</sup> in a paper on Spinal Arthropathies, deduces the following practical facts: First, regarding the period of development. The tabetic arthropathies may occur independently, or precede the active symptoms of locomotor ataxia. Then, again, they may develop suddenly, late in the course of a posterior spinal sclerosis.

He considers that the peripheral expression of central nerve irritations is characterized by the following changes found in the structures of the various articulations: (1) A chronic asthenic hyperemia of the synovial membranes; a hydrarthrosis. (2) An interstitial atrophy of the epiphyses. (3) A fungous or rarefying epiphyseal hypertrophy. (4) The formation of osteophytes and bony stalactites. These various joint expressions characteristic of spinal arthropathies may exist separately, but are usually combined in the same subject.

They may readily be distinguished from the common inflammatory lesions by the total absence of the reflex neural phenomena, that is, of pain, both reflex and local, the apprehensive state regarding joint-movements, and the reflex or tetanic spasm of the muscles, always associated with joint arthritis. There is some difficulty in differentiating the affection from malignant disease, but a careful inquiry into the history and course of the lesion, and the presence or absence of central disturbances, are our most reliable guides.

The progress of the arthropathies is essentially chronic. Occurring not infrequently early in the history of a tabetic lesion they slowly increase, with occasional exacerbations, and years elapse before fully matured.

A rapidly developing arthropathy may be associated with the later stages of an ataxia. Their course is self-limiting, though never reparative.

#### TREATMENT OF RICKETS.

Hagenbach<sup>6</sup> reports success with the phosphorus treatment of rickets, especially in cases of rickets of the skull and in spasm of the glottis, and from the results he has seen he is inclined to regard phosphorus as a specific in rickets.

#### SPINA BIFIDA.

Turreta<sup>7</sup> reports the successful treatment of a case of spina bifida in a child two months old. The tumor was situated in the region of the lower cervical vertebra. On exploratory puncture a clear fluid, with an alkaline reaction, was evacuated. On deep pressure the tumor became somewhat smaller, and at the same time a slight tremor of the lower extremities was observed. An elastic ligature was placed around the pedicle of the tumor. During the first five days a slight elevation of temperature was noticed, with vomiting, trembling in the extremities. After that the condition was normal.

At the end of twelve days the ligature fell off with the tumor, and complete healing at the end of twenty-seven days.

#### SURGICAL MANAGEMENT OF RHACHITIC DEFORMITIES OF THE LOWER EXTREMITIES.

In a paper on the above subject Dr. V. P. Gilney<sup>8</sup> draws the following conclusions regarding operative treatment of bow-legs and knock-knees: (1) Children under two years of age presenting bow-legs or knock-knees should not be subjected to operation or to mechanical treatment unless the deformity is very exaggerated. (2) Children under three years with only a moderate degree of deformity may be safely left to nature. Dr. Gilney further says: "In bow-legs we have often a general curve, extending from the perineum to the ankle, without any sharp deviation whatever, and again there are many where the tibia and fibula are sharply curved at the junction of the middle with the lower third of the leg. In the former, nature, according to my observation, corrects the deformity so thoroughly that we cannot find traces of the original deviation; in the latter, if treatment is rejected, the curve nearly always remains, and, as the child grows in height, the curve becomes longer and less conspicuous."

In the former (general curve of thigh and leg) he rarely uses apparatus; in the latter (curvatures of leg) he rarely omits apparatus. Regarding the employment of manual force, Dr. Gilney uses it in the correction of deformities:—

(1) In patients whose parents are unable to buy apparatus and too improvident to give any attention to its care.

(2) When one has little time in which to effect a cure.

(3) In cases where the bones yield to such force, the other two conditions being present.

Dr. Gilney's rule is to apply apparatus to bow-legs if he finds the bones can be sprung with moderate manual force. This in children under five years of age.

His experience in osteotomies he presents as follows:—

(1) Exaggerate the correction of the deformity.

(2) Examine the limb at the end of a week to ascertain whether the amount of correction gained is the amount desired.

(3) Do not hesitate to refracture by manual force if it is necessary.

(4) With strict attention to details in operating, and in the use of good plaster-of-Paris bandages well applied, cases can be treated in a dispensary nearly as well as in a hospital.

After operations three months' support in some form of splint is not too long.

#### CONGENITAL DISLOCATION OF THE HIP, RESECTION.

Hensner<sup>9</sup> showed at the meeting of Surgical Section at Magdeburg a girl twenty years of age who was born with a double dislocation of the hip and suffered, in consequence from the distortion, a certain amount of fatigue and inability for active work. Treatment by extension was tried without

<sup>5</sup> Philadelphia Medical Times, February 14, 1885, p. 175.

<sup>6</sup> Centralblatt f. Chirurgie, No. 47, p. 797.

<sup>7</sup> Centralblatt f. Chirurgie, No. 47, p. 797, 1884.

<sup>8</sup> New York Medical Journal, November 25, 1884, p. 181.

<sup>9</sup> Centralblatt f. Chirurgie No. 18, 1884, p. 301.

success and resection was decided upon. The ligamentum teres was found to be wanting; the trochanter, neck, and head were smaller than normal; the head was egg-shaped in length, and flattened on the side next the pelvis and rough. The neck was not at right angles with the shaft as has been stated to be the case usually in congenital dislocation, but was at an obtuse angle with the shaft. The acetabulum was exceptionally normal in size but was flat at the upper and posterior corner.

At the operation the acetabulum was deepened by a chisel and the stump of the femur fitted into it.

When shown the patient could walk, with the aid of a stick, half an hour without fatigue.

#### CONGENITAL DISLOCATION OF THE HIP.

In Professor Bennett's<sup>11</sup> inaugural address before the Surgical Section of the Academy of Medicine in Ireland, he vigorously attacks about all of the prevailing theories regarding the causation of congenital dislocations of the hip.

He assumes in his paper and believes that the deformity is a part of the same class as congenital dislocation of the shoulder, elbow, and congenital club-foot.

He further assumes that the specimens on which his address is based are simply one kind; and for practical surgical purposes considers that a congenital dislocation of the hip is a single dislocation varying in degree, but not in kind. He believes that Hutton's observation is a most valuable one, namely: that the axis of the neck of the femur in congenital dislocations is advanced by rotation through an angle of more than a quarter of a circle; and so in all these cases the limb existed in a condition perfectly free from any appearance of rotation inward.

He found no evidence supporting Ammon's theory of arrest of development in his dissection; but inclines to Guérin's theory that during fetal existence some irregularity of nerve action occurred, which caused a spasmodic action of certain sets of muscles, which retraction caused displacement of the head. He was much impressed with the destruction of fibres of the gluteus maximus muscle.

Mr. Brodhurst's mechanical theory or abnormal labor theory he considers "a blank dogmatic assertion."

The gist of the paper is a plea for the early treatment of this congenital deformity.

#### AFTER TREATMENT OF RESECTION OF THE HIP.

Kinne,<sup>12</sup> after excision at the hip-joint, attempts to avoid the result of a cure with a sinus by leaving the wound open, using no sutures and leaving an antiseptic tampon of carbolic gauze in the wound, putting iodoform on the wound. On the first day the tampon is not to be removed but left to be absorbed by granulation. In ten cases, by this way, seven healed without a sinus, and three formed in the earliest case three years and in the latest case one and one-fourth later, and in all of the cases the disease at the time of operation was well advanced. In the three of the operations, as the advantages of the method, not healed.

<sup>11</sup> Kinne, *A Journal Medical & Surgical*, January, 1885, p. 11.

<sup>12</sup> *Deutsche Medizinische Wochenschrift*, 1884, No. 20.

prompt arrest of hæmorrhage, good drainage, complete juxtaposition of the antiseptic with the wound, diminution of the pain caused by pressure of the upper end of femur against the pelvis, and a solid and firm cicatrix.

#### DUPUYTREN'S CONTRACTION OF THE PALMAR FASCIA.

Seventy cases form the basis of a paper, by Noble Smith, on this subject.<sup>13</sup>

Dr. Smith's attention was directed to the following points: (1) The supposed immunity of females from this affection. (2) The cause of the malady. (3) Its treatment.

The statement is commonly made that Dupuytren's contraction of the palmar fascia is found only in men. Noble Smith found, out of 444 women examined, eleven well-marked cases, and fifteen cases where there was induration, thickening, and contraction of the fascia alone.

Smith<sup>14</sup> throws out rheumatism and gout as causes of this affection. He could find no special general condition of health which might have given rise to the disease.

His cases were mostly old people, the average of age being seventy-three. In thirty-two cases out of fifty-five, the right hand was affected. The much greater frequency with which the right hand suffers leads one to suspect that use has a material influence in causation.

In the last forty-five cases he examined, Dr. Smith found the tendon of the palmaris longus muscle tense and prominent; he suggests that perhaps contraction of this muscle may be the first morbid condition, and by its constant action irritate the fascia and so cause it to thicken and contract. Dr. Smith has seen several cases where injuries to fascia have produced contractions identical with, or very similar to, Dupuytren's contraction.

Regarding treatment, Smith finds that forced extension of the fingers is not very successful. Subcutaneous section of the fascia is the only operation which promises relief, but such relief has not always been permanent. He favors making as few incisions as possible rather than multiple. He believes that the separation of the cut ends of the fascia is of great importance, as it prevents remission and recontraction. He suggests, as an early measure of treatment, division of the tendon of the palmaris longus muscle where it is tense.

F. R. Fisher, in a note in the next issue of the *British Medical Journal*,<sup>15</sup> states that he has "examined a good number of cases in the early stage, and has never found the palmaris longus muscle in an abnormal condition."

Dr. Fisher further disagrees with Noble Smith's deductions, in that he believes in many small incisions, as the "indurated fascia is cut up into small pieces, and thereby becoming absorbed, the chief cause of relapse is removed."

#### DUPUYTREN'S CONTRACTION OF THE FINGER.

Reeves<sup>16</sup> recommends open incision (under antiseptic precautions) of this deformity, and reports a

<sup>14</sup> Adams's theory. *British Medical Journal*, August 23, 1884, p. 306.

<sup>15</sup> *British Medical Journal*, February 14, 1885, p. 32.

<sup>16</sup> *British Medical Journal*, March 7, 1885, p. 481.

case where this was successfully done. He claims that the cure is more certain and the recovery more rapid than by tenotomy. After incising the skin, the shortened band, which, after being isolated, should be divided and the finger forcibly straightened, the incision is sewn together.

#### RESECTION OF WRIST.

Resection of the wrist in fungus osteo-arthritis,<sup>17</sup> Gangolphe has collected Ollier's resections at the wrist. Of these, seventeen in number, three were respectively sixty-six, forty-six, and fifty years old. Eight were between twenty-five and forty. Five were between twenty and twenty-five. One was fourteen years old. The operation was regarded as indicated as soon as the tuberculous nature of the disease is established without doubt, when suppuration is present, and all non-operative measures have proved of no avail; an early resection naturally gives better results than a later one, and the author is inclined to believe that the poor results hitherto following resections of the wrist were due to a long postponement of the operation. An active affection of the lungs is a contra-indication of the operation, but a torpid tuberculosis of the lungs does not contra-indicate the operation and the condition of the lungs may be benefited by it. Age appears not to be a contra-indication, the best result that was obtained being in a man fifty years old.

The operation is best done by a dorsal incision, but, in addition, lateral incisions were made in all cases to give drainage, the ulnar opening being so free as to often be of use in the operation. Usually all the carpal bones need to be removed, though the pisiform and the os magnum may sometimes be removed. Ollier usually cauterizes the parts chiefly affected with the actual cautery. Drains are to be inserted and a tampon of iodoform gauze and Liston gauze dressing is applied around the whole. The dressing should be changed as little as possible. The after treatment is very important and is directed with a view toward the future usefulness of the hand. This after treatment should not be simply to repair by curing the incompleteness of the first operation, but with a definite aim toward a solid cicatrization with the continuation of the drainage-tubes for a long time, sometimes months, and a systematic cicatrization of the fistulae, with nitrate of silver, iodine, etc., to promote healing. The hand should be supported by a rest (a plaster-of-Paris bandage) which would allow free play to the fingers.

The results gained in the seventeen cases were reported to be excellent. Subsequent amputation was needed in none; all recovered with useful hands, being able either to write or to carry out light work, and, in some cases, to lift weights. Motion at the finger-joints and at the wrist became quite free.

#### OSTEOTOMY AND OSTEOTOMY.

Boeckel<sup>18</sup> summarizes his results as follows:—

In 120 patients with distortion of the extremities osteoclasis was needed thirty times. The operation was performed on patients of from eighteen months

to eight years, with twenty-seven successes. Of the three remaining cases, a periostitis was brought about in one (a case of knock-knee), which needed incisions before recovery; in a second case, non-union occurred, which lasted for a long time, and in a third, knock-knee, the ligaments of the knee were so weakened that a support had to be worn; thirty-two osteotomies were performed; (eighteen rickety curves of the leg, ten genu valgum, three badly united fractures, one subtrochanteric osteotomy) and were all successful: twenty-three healing by first intention, under two or three dressings; six with slight, two with profuse suppuration; one after an attack of erysipelas.

#### A MODIFICATION OF THE METHOD OF BRISEMENT FORCÉ IN THE STRAIGHTENING OF A CONTRACTED KNEE.

Schaechter<sup>19</sup> advocates in brisement forcé of the knee-joint, in order to avoid the fracture or the total subluxation of the tibia backward, which sometimes happens when the leg is used as a lever in forcible straightening, the method introduced by Kovács. A splint of sufficient strength is fastened by bandages on the front of the leg, such a way that the upper end reaches above the knee, resting upon the condyles. On forcible rectification the pressure upon the back of the leg would tend to prevent the backward dislocation of the tibia, a distortion which is still further prevented by the pressure on the condyles.

#### THE RADICAL CURE OF CLUB-FOOT.

The removal of a cuneiform osseous wedge from talipadic feet was advocated in a paper by Mr. Richard Davy, at the Royal Medical Chirurgical Society.<sup>20</sup> Nineteen of the writer's cases were boys and four were girls. The open-air method of cicatrization had been practised in all of his cases. The mortality was less than four per cent. Two cases were submitted to the double operation at one sitting. Fourteen were cases of talipes equino-varus, ten were cases of talipes varus, and two were cases of equinus. The oldest patient was twenty years old, the youngest fifteen months. The average stay of the patient in the hospital from the date of operation to that of discharge was seventy-seven days. A shortened symmetrical foot is left, which is far preferable to a stump. The patients become plantigrades, dispense with instruments, and perform their ordinary duties.

Six specimens of the osseous wedges removed (all in one block of bones) showed as component parts the individual bones of the transverse tarsal joint; one specimen showed portions of the astragalus, os calcis, the bases of the four metatarsal bones, and the internal cuneiform bones, and the whole of the scaploid, cuboid, and two outer cuneiform bones.

In conclusion, the author put forward this excision of an osseous wedge as mainly applicable to inveterate cases; he was inclined to plead for its adoption in young persons under certain circumstances.

He summed up in favor of the operation as follows: "In obstinate club-foot, where osseous distortion has occurred, a definite mechanical operation

<sup>17</sup> *Revue de Chirurgie*, 1884, No. 5.

<sup>18</sup> *Centralblatt f. Chirurgie*, March 11, 1885.

<sup>19</sup> *Centralblatt f. Chirurgie*, No. 45, 1884, p. 745.

<sup>20</sup> *Lancet*, February 11, 1885.

with definite surgical landmarks performed on the tarsal bones has led to definite results. Mr. R. W. Parker, who has paid much attention to the anatomical condition of club-foot, stated that with considerable opportunities he had not seen any cases of talipes in young subjects which had not yielded to very much milder measures than those proposed by Mr. Davy.

"In dissecting the talipædic feet he had found though the astragalus was usually altered in shape, that this was not invariable; on the other hand, in all cases the ligaments were shortened, and in severe cases, even after the removal of all the muscles, the foot could not be straightened on account of the shortening of the ligaments.

"He was thus led to think that in the treatment of talipes more attention should be given to the ligaments than was usually done, and that many of the inveterate cases met with in practice were due to the shortening of the ligamentous structures on the inner side of the feet. If the ligaments and muscles were equally stretchable (which is not the case) we should naturally expect more stretching in the muscles than in the ligaments by reason of their greater length."

Vogt states<sup>21</sup> that, "In all severe cases of talipes varus and valgus (congenital), we should begin immediately treatment on new-born children by extirpation of the astragalus. Only in this way can we attain rapidly and certainly a permanent cure of the deformity of the foot. Only so few months are needed for the orthopædic after treatment (after operation) as would otherwise require years."

#### ACUTE OSTEOMYELITIS OF THE SURFACES OF BONES.

Bergmann has collected twenty-five cases (eleven of the ilium) of osteomyelitis of the flat bones. In these the osteomyelitis appeared to be the primary affection and the periostitis secondary. In some the affection appeared to be primarily situated in the adjacent long bone and to have extended secondarily to the surface of the flat bone, but in the greater number the destructive process appeared primarily in the latter.

The disease hitherto was considered as eventually fatal, but the writer expects by thorough extirpation of the focus of inflammation to obtain better results.<sup>22</sup>

#### INFECTIONS OSTEOMYELITIS.

Rodet<sup>23</sup> claims in a series of experiments at Lyons to have demonstrated a specific micrococcus of osteomyelitis. Taking the pus of infectious myelitis he made a culture of an orange-colored micrococcus and on injecting this in the veins without any injury the following symptoms were developed: In the most acute cases death took place two to three days after the injection, and thickening of the periosteum of the diaphysis near the epiphyseal line was found, together with small cheesy abscesses of the muscles and hyperæmic spots in the kidney. In the more chronic cases the process was limited chiefly to the bones. In many instances only a roughness of the surface of the bone was observed or an abnormal softness of the surface, but in the worst

cases suppuration, destruction of bone, and small sequestrum; small foci of orange-colored micrococci similar to those found in the cultured could be seen on microscopic section. No disease of the epiphysis took place.

#### MULTIPLE EXOSTOSES.

Seidel<sup>24</sup> reports a case of multiple exostoses with an arrest of growth, a companion to one previously reported by Volkmann. The individual was sixteen years old, who for six years noticed a swelling of the left forearm. Several other exostoses were formed on the lower extremity and elsewhere. The largest of these were on the lower epiphyses of the femora and the upper of the tibia; smaller ones were to be found on the lower end of the tibia, clavicle, scapula, upper arms, and ribs. The forearms were shorter than normal in relation to the length of the upper arms, and the amount of pronation and supination limited, and the ulna was much shorter than the radius. Operative measures were taken to remove the exostoses which united the radius and ulna. These were successful as far as removal of the deformity is concerned.

#### NORMAL INCREASE OF WEIGHT IN CHILDREN.

Malling-Hansen,<sup>25</sup> as director of the Royal Deaf and Dumb Institution, has examined 130 children, weighing them at different times. The boys were weighed at 6 A.M. and 9 P.M. The girls were weighed once a day, at 2 P.M. He found that a child might weigh from one to two pounds heavier at night than in the morning, and be more than one pound and a half lighter in the morning than it was the evening before exercise. Bathing did not influence the weight. There was always an increase after a full meal. He found that there were three periods in which the weight varied: first, a period of decrease from the middle of May in each year to the middle of July; a period of increase of great importance from the middle of July to the middle of November; and then a period in which the child increased slightly, but often remained stationary, and might even lose in weight, from the middle of November to the middle of May. Temperature had an effect upon increase and decrease, increase of temperature being accompanied by increase in weight, and *vice versa*. Boys consumed one fifth more than girls.

#### IMPROVEMENT IN THE CONSTRUCTION OF THE HIP-SPLINT.

A. B. Judson<sup>26</sup> describes an improvement in the construction of a hip-splint. He states "that the object of this form of construction is to diminish the weight of the hip splint, while retaining its strength and inflexibility, by disposing the metal so that it shall resist to the best advantage the strain to which it is subjected.

"When a hip-splint is made strong enough in the pelvic band and upright to perform the functions of an efficient ischiatic crutch, preventing the patient's heel from reaching the foot-piece of the splint in walking or running, it is found necessary to give considerable weight to the apparatus when constructed, as it often is, with a round upright, or with

<sup>21</sup> Centralblatt f. Chirurgie, No. 23, p. 360.

<sup>22</sup> Centralblatt f. Chirurgie, No. 6, p. 162, 1884.

<sup>23</sup> Comptes rendus Académie de Médecine, 1884, II., No. 11.

<sup>24</sup> Centralblatt f. Chirurgie, No. 1, 1885, p. 12.

<sup>25</sup> British Medical Journal, September 20, 1884, p. 68.

<sup>26</sup> New York Medical Journal, January 24, 1885, p. 111.

the flat side of the upright toward the patient's limb. If the upright is made flat and attached to the pelvis band in such a way that its edge is toward the patient, it is practically inflexible, and the amount of steel used in its construction may be greatly reduced."

Then having the rack (for extension) at the upper part of the splint further reduces the weight of the apparatus by allowing the upright to taper rapidly toward its lower end, and also puts the heavier portion of the upright nearer the centre of gravity of the body, thus rendering it more easily carried.

#### AFFECTIONS OF THE TENDO-ACHILLIS.

Kirmisson<sup>25</sup> mentions a case of what has been termed by Raynal peritendinous inflammation of the tendo-Achillis. The patient suffered pain in the region of his tendo-Achillis during an attack of gonorrhoeal rheumatism. Later an induration appeared, which subsided finally under rest in bed and painting with iodine. In a second case the reporter observed a double fibroma of the tendo-Achillis in a man twenty-nine years of age, of five years' duration. The tumor was painless, and stationary as to growth. No treatment was attempted.

### Reports of Societies.

#### NEW YORK ACADEMY OF MEDICINE.

STATED meeting April 2, 1885.

#### ANTIPYRIN AND ITS EFFECTS.

DR. WILLIAM H. DRAPER read a paper on this subject. Having stated that, while little had been added to our knowledge of the essential nature of fever, the means of controlling it at our command were continually enlarged, he took up the consideration of antipyrin as an antipyretic agent. It was one of the many derivations of coal-tar, and in experiments upon animals had been found to have remarkable power in reducing temperature. In very large doses it produces death by cardiac paralysis, and in somewhat smaller ones irritability of the nervous centres followed by paralysis.

Filchne, of Erlangen, was the first to use it in the treatment of fever, and his plan was to give it in two-gramme doses, repeated at intervals of an hour, until six grammes had been taken. In his cases it was noted that when the temperature again went up, after having been reduced by the agency of the drug, the rise was not accompanied by a chill, as was the case when kairin was used as an antipyretic. Marked sweating, however, was produced in many cases.

Having referred to the results obtained by Alexander, Guttmann, Pappenheim, and other observers, he said that his own experience with the use of antipyrin had been principally at the New York Hospital, and, for the most part, confined to cases of typhoid fever. When he went on duty at the hospital on the first of October last, he found that his predecessor in charge of the medical wards, Dr. Peabody, had already been employing it to some extent, although he had been somewhat embarrassed on account of the short supply of the article in

New York in the early part of the autumn. He had, however, been much impressed with its antipyretic power, and had also noted that, as a rule, it seemed to have a very tranquilizing effect upon the nervous system in four patients. He had himself observed its effects upon twenty cases of typhoid fever, of which seventeen were in males and three in females. Of the twenty, five died, the mortality thus being twenty-five per cent.

The highest temperature that was noted in any one of the fatal cases was 107.6°, and this occurred on the twenty-fourth day of the disease. In one instance the temperature promptly fell to 102° under the use of antipyrin when baths persistently tried had failed to reduce it below 104°. In the case among those which recovered in which the temperature was highest, the range was from 103° to 106.6°. Vomiting was a frequent symptom, and in the fifteen cases which recovered diarrhoea was present in seven, while there was constipation in eight. Sweating was noticed in a number of cases, but the nervous symptoms were notably few. All his typhoid-fever patients were treated either with applications of cold, in the form of baths or sponging, or with antipyrin. As a rule, the method of Filchne, of Erlangen, was followed in giving the latter. The patients were usually given seventy-five grains, divided into two doses of thirty grains and one of fifteen grains, which were given at intervals of one hour.

It was rarely necessary to use more than 150 grains of the antipyrin in twenty-four hours, and in almost every case in which it was employed it was found that the general average of the temperature was from two to three degrees lower than could have been expected had no effort been made to control it. As a rule, the pulse followed pretty closely the temperature curve. In every instance in which it was employed the temperature was lowered. In one case no effect was produced when the remedy was administered by the stomach; but when it was given hypodermically the temperature rapidly fell. There was never any marked depression of the heart's action produced by it, and one of the most noticeable of its effects was the prompt cleansing of the tongue which followed its use. There was sweating in six of the cases. Nervous symptoms were almost invariably quieted by it, and in only a single instance did it seem to occasion depression of spirits. In six cases it produced an erythematous rash resembling measles, and in one case a macular eruption of a somewhat purpuril character. In none of the cases, except those in which parenchymatous nephritis was associated as a complication, was any change in the character of the urine noticed.

Among the fatal cases the largest quantity taken by any one patient was about 350 grammes, during a period of thirty days, while among the cases that recovered the largest quantity was 334 grammes. It was given in 140 doses during a period of twenty-three days. The most marked fall of temperature noted in any case was from 103.8 to 98°. In three instances the effect of cold baths and antipyrin was contrasted. In the one of these in which the contrast was most marked the baths failed to reduce it below 104.3°, while the antipyrin brought it down to 102.2°. In

<sup>25</sup> *Centralblatt f. Chirurgie*, No. 36, 1884, p. 608.

the second case the lowest temperature reached under the use of baths was  $102.4^{\circ}$ , while under that of antipyrin it fell to  $101.2^{\circ}$ . In the third case the difference was not so marked. In a case of puerperal septicaemia, under Dr. Peabody's care, the remedy had been very successful in reducing the temperature.

Dr. Draper said he had also used antipyrin in pneumonia, scarlet fever, and tuberculosis, and had found that it invariably lowered the temperature and contributed in other ways to the welfare of the patient. His observations had thus completely confirmed those of European physicians. In estimating the real value of the drug, it could only be commended at present as a sure and apparently safe means of reducing temperature. It did not cut short or cure the disease; but it ought not on this account to be condemned.

At present we had to be content with controlling the symptoms which caused such discomfort to the patient and often endangered life itself. Antipyrin was not an antipyretic in the sense that quinine and the salicylates were. In the affections in which they exercised their full effect they were ideal antipyretics. Antipyrin, on the other hand, smothered, but did not extinguish, the fires of fever. In certain instances it produced a lowering of temperature such as was only seen in collapse under ordinary circumstances, but with this there was none of the depression seen in true collapse. As to the manner in which antipyrin acted in reducing temperature it was at present idle to speculate, but from the fact that it was liable to cause vomiting, sweatings, and collapse of the temperature it seemed probable to him that its special effect was on the nervous centres.

Dr. Draper's conclusions were as follows:—

(1) In antipyrin we have an efficient means of reducing temperature.

(2) It is an apparently safe means, if prudently given and carefully watched.

(3) While it does not modify or abate febrile diseases, it unquestionably adds greatly to the comfort of the patient.

(4) Exceptionally it produces unpleasant effects, which more than counterbalance its beneficial action.

(5) Further experience with it and modifications of the present mode of its administration may render it a precious contribution to our means of treating fevers.

Dr. WEBER said that he had employed antipyrin thus far in fifteen cases. There had been no typhoid fever among them, but there were cases of pneumonia, bronchitis, and scarlet fever. The remedy had proved very successful in reducing temperature; so that he had not been disappointed in it in this direction in a single instance. He would select two or three cases as examples. The first was one of double pneumonia, in a child four and a half years old. The temperature was  $105.5^{\circ}$  and the patient violently delirious. At 1 p.m. half a gramme of antipyrin was given *per rectum*, and at 1.30 p.m. another half-gramme was given in the same way; and by 5 o'clock the temperature had fallen to  $102.5^{\circ}$ . The next day two doses were again given, but by the stomach, and half the

quantity was used each time. Resolution then occurred and the remedy was not again required.

The second case was one of scarlet fever and the antipyrin was given for the purpose of keeping the temperature within bounds. The patient was a child two and a half years old, and the temperature when the treatment was commenced was  $105^{\circ}$ . In this instance he followed a plan of administration which he hit upon himself, but which he afterward saw mentioned as having been used with good effect at the Dresden City Hospital. It was to give the remedy in smaller doses repeated at intervals of two or three hours throughout the day, and in this case the method was very successful. The third case which he mentioned was that of a lady forty-three years of age who had a pneumonia of the upper lobe of the left lung, with pleuritis of the right side, and it was the third attack of pneumonia in which he had attended her. She did perfectly well for a day or two; but on the third day he found her with a temperature of  $101^{\circ}$  and a pulse of  $110^{\circ}$ , a dusky hue of skin, and a generally adynamic condition. He ordered her sixty grains of antipyrin, to be given in three doses of twenty grains each at one, two, and three o'clock respectively, and at 2.30 there was a little vomiting. Afterward there was sweating, and the temperature was soon reduced to  $100.5^{\circ}$ , while the pulse came down to  $96^{\circ}$ . After that the temperature did not rise above  $101.5^{\circ}$ . He thought it advisable to begin with small doses, say half a gramme (*per rectum*), to children and one gramme to adults, and afterward increase it if this should be necessary. In this it would be possible to avoid a rapid and perhaps dangerous fall of the temperature, such as has been noticed by some observers. In six cases at the Dresden City Hospital the temperature was reduced to  $92^{\circ}$  or  $93^{\circ}$ .

Dr. BOLDT spoke of two cases of puerperal septicaemia in which he used doses of four, instead of two, grammes of antipyrin, which produced considerable prostration and symptoms resembling those of carbolic-acid poisoning, the patients becoming semi-comatose. He had found that the remedy produced its action in from forty-five minutes to an hour after being taken, and that its effects did not continue for more than three or four hours. It was his practice to commence with twenty or thirty grain doses, and increase the quantity afterward, according to the necessities of the case. He had not observed the same relation between the pulse and temperature after the exhibition of antipyrin, of which Dr. Draper had spoken, and in the two cases of puerperal septicaemia referred to there was no effect whatever produced by it upon the condition of the pulse.

Dr. KINNICUTT said that he had used antipyrin somewhat extensively both at Luke's Hospital and in his private practice, and that the effects caused by it were for the most part precisely similar to those observed by Dr. Draper. Among the affections in which he had employed it were facial erysipelas, scarlet fever, pneumonia, pleurisy, phthisis, and intermittent fever. Gastric disturbance he had found an exceptional occurrence. In one case, and only one, he had noted a chill in connection with the rising temperature, as was so frequently met with when kairin was used as an antipyretic. He

expressed himself as particularly pleased with the certainty of the action of the remedy in controlling the usual afternoon rise of temperature in cases of phthisis. In this affection it had been claimed that antipyrin was contra-indicated on account of the sweating which it was likely to produce; but in his experience this symptom was as often absent as present in tuberculous patients using the remedy. In one case of pneumonia a dose of twenty grains of antipyrin had caused the temperature of collapse ( $95^{\circ}$ ); but there were no other symptoms of collapse whatever, the patient expressing herself as feeling greatly relieved, and the general condition being perfectly satisfactory. To children he was accustomed to give two doses of a decigramme each for each year of the patient's age; and he had found it a very useful remedy, particularly in controlling the high temperature of scarlet fever.

Dr. PEABODY thought that the lack of effect observed in some cases where antipyrin was given might perhaps be explained by a fact which he had recently seen stated in the German journals, namely: that the drug was now largely adulterated. In his earlier experiments with it he had never failed to produce rapid reduction of the temperature; but during the last six weeks he had been more than once disappointed in obtaining the desired effect. For instance there was now at the New York Hospital a negro with a temperature ranging from  $103^{\circ}$  to  $106^{\circ}$ , and for the past two days he had given him seventy-five grains of antipyrin a day, in three doses, without affecting the temperature the fraction of a degree. At all events, he thought that we did our patients no harm in ordinary cases, in giving this remedy, and he had never once seen it reduce the force of the heart's action. It would, perhaps, be of interest to know that it could be administered hypodermically very readily and without fear of producing injurious local effects. It was very soluble in hot water and had no tendency to recrystallize. In cases, therefore, where it produced vomiting, or other unpleasant results, when given by the stomach, it could be used hypodermically instead. He had tried antipyrin in almost all of the ordinary febrile diseases, and had found that it sometimes reduced temperature when this result could be effected by no other means. Thus, in one very stout young woman suffering from typhoid, with a temperature of  $105^{\circ}$ , where long-continued and often-repeated cold baths had no effect whatever (apparently on account of the thick layer of adipose tissue on the patient's body preventing the influence of the cold reaching the interior), the temperature was promptly reduced by the use of antipyrin. The remedy, therefore, he thought, was unquestionably worthy of being further tested.

Dr. DRIVER said that he had himself adopted the plan of administration suggested by Dr. Weber, and in one case he had found that twenty grains given twice a day had contributed very greatly to the patient's comfort and welfare. All that we could say of antipyrin at present was that it was a very efficient means of treating a symptom. But this symptom was often one of very great importance, and in typhoid fever particularly the long-continued high temperature was liable to constitute

an element of grave danger. By controlling this, therefore, one could unquestionably save the life of the patient in a certain proportion of instances.

#### CLINICAL SOCIETY OF THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL.

MEETING of February 7, 1885. Dr. WILLIAM PORTER in the chair.

Dr. WILLIAM H. PORTER opened the discussion with a paper upon

##### SYPHILITIC PNEUMONIA AND PHTHISIS.

After directing the attention of the Society to the contradictory nature of the literature of this subject, he said that his studies, based upon a large number of clinical and pathological cases, tended to show that syphilitic lesions of the lungs, as well as of all the viscera, were far more common than was generally supposed. His records showed a greater liability among females, and that it was often inherited. He thought that fifty, if not a larger, per cent. of all cases of phthisis were of this origin. Its pathological anatomy was distinctive, although it closely resembled that of tubercular phthisis. The characteristic lesion was a decided thickening of the pulmonary tissue, commencing at the apex, and descending with many circumscribed zones of consolidation, which ranged in size from a millet seed to a hen's egg, or even larger. These foci were cheesy in the centre, and sometimes became softened and formed cavities, but were more frequently encapsulated as they expanded. The capsule was composed of highly vascular and concentrically arranged layers of fibrillated connective tissue, and the walls of all the bloodvessels were greatly thickened by a peculiar hyaline metamorphosis. The walls of the vessels were not involved in true tubercle.

The symptoms of syphilitic pneumonia or phthisis were a mild cough with copious expectoration, dyspnea, hæmoptysis, great loss of strength, but little or no emaciation, and, as a rule, little or no rise of temperature, even when cavities were formed. There was a peculiar tenderness of the sternum and of the tibial crests, which he regarded as pathognomonic of syphilis. The physical signs were peculiar and diagnostic. Inspection showed that all the accessory muscles were forcibly contracted upon a forced inspiration. Palpation revealed an increased vocal fremitus, and varying degrees of dullness were made out upon percussion. Prolonged and harsh respiratory murmurs, with a decided interval between the sounds of inspiration and expiration, and often broncho-vesicular breathing, which closely resembled amphoric breathing, with an absence of both dry and moist râles, but the evidence of cavities, when present, were distinguishable upon auscultation.

The diagnosis was based (1) upon the abundant muco-purulent expectoration without any sign of softening, (2) upon the weak and debilitated condition and a good rational history of phthisis, but with a good physique, (3) upon the pronounced

dyspnea without the evidence of either cardiac or pulmonary obstruction to the circulation. (1) Upon the peculiar tenderness and reaction to pressure upon the sternum and crests of the tibia. (5) Upon the unique train of physical signs. (6) Upon the ready response to treatment.

The prognosis, if the trouble was made out early and treated not like ordinary phthisis, was good. He had found the best treatment to be one sixteenth of a grain of the biniodide of mercury, with five to ten grains of the bromide of ammonia and ten to twenty of the iodide of potassa, at each dose. This should be given three times a day. The ammonia appeared to act upon the other two elements in the prescription just as a thorough trituration did upon calomel, namely, it appeared to increase their power, and consequently it was possible to do with a smaller dose than would otherwise be necessary.

He grouped his conclusions under six distinct classes:—

(1) *Etiology*: the pulmonary lesion attributable to syphilis was very common, more so in females than in males; the largest number of cases were between the ages of twenty and fifty, and it was more frequently inherited than acquired.

(2) *Pathology*: it was more frequently found at the apex than at any other single point in the lungs; that both lungs were usually involved at the same time; in the early stages it was a pneumonic process, but later formed cavities and assumed a phthisical type; that there was a strong resemblance, but a positive and readily appreciable difference, between the syphilitic and tubercular lesions, both gross and microscopic. There was a positive anatomical difference between miliary tubercle and syphilitic gumma tubercle, the latter having a definite capsule with thickened bloodvessels, and a tendency to become encapsulated and enlarged, which was never the case with miliary tubercle.

(3) *Symptoms* were peculiar and distinctive: the rational signs were often those of ordinary phthisis, while the physical signs were negative and not pathognomonic.

(4) *Diagnosis* rested mainly upon the peculiar rational history and physical signs, the extreme dyspnea and periosteal tenderness, and the absence of an increased temperature.

(5) *Prognosis* depended upon the recognition of the condition in its early stages and the plan of treatment pursued; very severe cases could be improved if not cured.

(6) *Treatment* should be anti-syphilitic; no other would be of any avail, and many cases were not apparently affected by the iodide of potassium alone, but rapidly improved under the combined action of the biniodide of mercury with the iodides of ammonia and potassa.

Dr. ELLIOT said that since the discovery of the bacillus tuberculosis by Koch, nearly all observers who had been at all careful in their methods of technique had succeeded in finding the microbe and in isolating it, so that they satisfied themselves that it had a separate identity. Others who were less careful in their methods of examination had found the bacillus, as they claimed, in various indefinite fluids, as water, normal sputa, urine, and expectoration from various forms of lung disease, and on

the strength of such cursory investigation had at once denounced Koch and his germ.

While careful observers were satisfied as to the identity of this germ, they were not agreed as to the part it played in the specific disease, tuberculosis. There was a tendency on the part of extremists to make us believe that many or nearly all cases of chronic phthisis were tuberculous, that nearly all enlarged glands were tubercular, and in no department were they so sanguine as in the chronic suppurative diseases of bone. They classified all cases of carious inflammation, of suppuration of the vertebrae, or in the bones of the joints, as distinctly tubercular, and would have the diagnosis based upon the discovery of one or two bacilli in an examination of from thirty to forty specimens. It seemed to him to be as unreasonable to classify all suppurative diseases of bone under the head of tubercular as it would be to so class all the chronic diseases of the liver.

But we know that the liver is subject to syphilitic infiltration, fatty degeneration, or to tuberculous deposit; was it not possible that the same variety of diseases could be engrafted upon a diseased bone? This seemed to be the more probable since recent histological researches had demonstrated that bone was similar to connective tissue, in which particles of mineral matter had been deposited, and like connective tissue it had its vascular and nervous supply; on this account, therefore, if on no other, it would be unreasonable to place all its affections in the category of tubercular. Of course this condition could be engrafted upon a suppurative disease of bone just as it might become the sequelae of acute lobar pneumonia, where resolution failing to take place an abscess formed and hectic and tuberculosis were developed. The autopsy in these cases showed that minute miliary tubercles were deposited about the abscess and sometimes in the other lung.

Extremists claimed that in all cases of chronic bone disease (suppurative) the bacillus tuberculosis was present and that in cases that tended to a cure they became encapsulated, but if a general tuberculosis intervened they escaped from their bondage and were carried to distant parts of the body.

Most cases of caries, however, recovered under the present modes of treatment; in fact, the general tendency was to recover. Not so, however, in former times when the more imperfect modes of procedure in these cases often enabled a tuberculosis to be set up and owing to imperfect nutrition and hygiene to cause awful havoc before its inroads were even suspected. Of course the condition incident to caries predisposed to tuberculosis. In our laboratories with their imperfect arrangements and uncertain methods consequent to the undeveloped state they were in we could not expect to refute the pathological findings of the completed and finely furnished laboratories of Europe. We should have to wait for more careful methods of examination, and for better facilities for checking and comparing our results with those obtained under these older and more complete advantages for the prosecution of pathological research. We should wait too, before accepting these views as absolute, until all the evidence was in our hands, which was not now the case. Competent observers must succeed in isolat-

ng the microbes and inoculating and so producing the disease before we would be able to say that the evidence was sufficiently strong to compel a universal acceptance of the theory. If this were done, he did not think that tuberculosis, especially in bone disease, would be found to be as common as many of the German observers would have us believe.

Dr. A. H. SARRI had had no personal experience with intra-pulmonary injections but was watching some cases on whom he proposed trying it. He considered that it was always desirable to watch a case upon whom it was intended to try a new remedy for some time before the exhibition of the drug, in order to appreciate the tendency of the disease.

Dr. M. PUTNAM JACOBI had treated a case of phthisis in this way some three or four years ago. There was a large cavity under the left clavicle and signs of softening in the right lung. The emaciation was extreme and the patient had been suffering for several years. It was impossible to say whether anything was accomplished by the treatment as the patient soon succumbed to the disease.

The needles were larger than those used by Dr. Phillips but they were never introduced the whole three inches of their length. Four to five days were allowed to elapse between the operations. There was very little pain experienced, and iodo cloths were immediately applied over the seat of puncture, as it was feared that a pleuritic inflammation might be set up. The patient raised a little blood after one of the injections but whether she had previously been subject to hæmoptysis did not appear in the history. It was evident that the injections if they had no beneficial effect did no harm.

Dr. S. S. BURR had occasionally seen a case of phthisis which seemed to be of syphilitic origin, but he had not found anything like the proportion indicated in the paper of the evening. He did not see the cases that came under his observation very early in the disease, as the patients when they came to a hospital were usually in the third stage. He did not consider that phthisis ever developed from acute lobar pneumonia unless tubercle were present, but he recalled one case in particular where an abscess and cavity had developed under the right clavicle after a pneumonia. He did not consider that the disease was directly inherited but that the had constitution which might predispose to its inroads might be. After the tubercles were developed our resources were very limited. He could only palliate the cough, give nourishing food, and suit the climate to the conditions of the case in hand. He considered it a mistake, however, to send advanced cases away, as many undertook the journey in search of health only to die soon after their arrival at the selected locality. He considered the division into three stages as entirely arbitrary and thought that two stages, those of consolidation and excavation, would answer the purpose as well if not better.

In the prognosis other things should be taken into consideration besides the physical signs. If the pulse was good and the fever slight, even though there was considerable consolidation the patient might be sent away with the prospect of some if not considerable benefit, but if with slight amount of consolidation there was present also a very weak pulse

and a good deal of fever then the prognosis was bad.

Dr. WM. M. LASZYENSKY, during a three years' experience in an asylum for the insane, had seen a number of cases of phthisis among the inmates, who, although excavations had taken place, had no rise in temperature: in fact, none of the rational symptoms of the disease, all seeming to be masked in the mental derangement. After death, however, the autopsy would show that they had been fairly well advanced in the disease.

Dr. J. M. W. KITCHEN had studied the disease entirely from a clinical standpoint, which in this day of pure culture and microscopical investigation was not very fashionable. His consideration of the subject had however led him to some pretty definite conclusions. He thought that the causes might be said to be three: predisposing, intermediate, and direct.

He was agnostic with regard to the direct cause, but did not consider Koch's theory proved as yet.

The predisposing cause was malnutrition in every case, while the cause of the malnutrition might be congenital, such as an anatomical malformation, as in a lung that was too large or too small; or it might be immediate, as in syphilis; or the cause of the malnutrition might rest with the heart or the nerves. He believed in hereditary habit and in an inbreeding of consumptives for generations, so that the descendants of phthisical parents, when exposed to direct cause, readily developed the disease. The intermediate cause he considered to be dependent upon an active or passive congestion, so that pulmonary phthisis was set up in a tissue that was in a bad state of resistance. Of course this was merely observation: he had no actual proof. He also considered catarrhal pneumonia as an intermediate cause, because when a lung was in this condition it soon became badly nourished and then could readily acquire tuberculosis, but tuberculosis might be present before the pneumonia. He had no faith in local applications in the treatment of this difficulty. It was, in fact, almost impossible to make any applications to the lungs in such a way as to exercise any curative influence, and he believed that the proper method was to build up the system as much as possible in the hope that a cure would follow as the resistance of the tissues was improved. He was himself an example, probably, of a cured case of phthisis, as several years ago he was told by several prominent physicians of the city that he was suffering with the disease. He had immediately started with the ideas of treatment just indicated, going to the country and working in the air among the flowers, etc., in order to place his system in the best possible condition to resist the progress of the disease and he was convinced that his recovery was due to this régime. He did not believe that there was any specific cure for phthisis even though it should be proved to be a specific disease.

Dr. Jacobi said that it was well known that children as a rule experienced a certain amount of immunity from the disease in question, as far as the lungs were concerned. Loewick found only one case in adults where the lung was not affected, while out of three hundred and twelve cases of phthisis in children, collected by Rillet and Barthet, forty-

seven were found with the lungs intact. This was in correlation with the theory which considered the infection of the lung as secondary to tuberculosis of the bone which was such a common condition in early life. Hueter advocated that one out of twenty cases might be averted by scraping the bone. Those who opposed this theory noticed how often caseous infiltration was present, and how many scrofulous children there were in whom phthisis did not occur. This was no argument, however, for tuberculous could be just as well confined to external manifestations without any complicating visceral lesion as could syphilis. The exciting cause was frequently a broncho-pneumonia, though in some cases undoubtedly the infection was first received by the glands.

DR. A. H. SMITH said that it seemed to him, to go back to the question of syphilis being a frequent cause of phthisis, that the study of the latter disease in rural districts remote from our large cities, where syphilis was not and had not been known for generations, such regions being quite in the range of the possible, would militate against the theory. Often, in these districts, phthisis prevailed perhaps to as great an extent as in the cities. He knew of a place where the population consisted of well-to-do farmers, whose ancestors had settled there a hundred or more years ago, and who had descended from that original stock with scarcely any admixture with other blood, where, although syphilis had been unknown for years, the great destroyer of life was phthisis.

He considered that malnutrition lay at the bottom of the development of the tuberculous condition, and he also considered that one factor having much to do with this malnutrition was ventilation, and he thought that any one who was familiar with life in the country would agree that, paradoxical as it might appear, while they had all outdoors to live in, they paid little or no attention to the proper ventilation of their dwellings and sleeping-apartments, living in reality in worse atmospheres than usually obtained in our large cities, and this caused, in his opinion, many of the pulmonary complaints which existed in those localities.

As bearing upon this subject, as well as upon a specific cause for the trouble, might be mentioned the fact that in many sections where phthisis had not existed, prior to their becoming resorts for such cases, the disease had now become indigenous to a greater or less degree. This was the case, he had been told, in Colorado, and the same thing was also shown in some of the South Sea Islands, where phthisis was absolutely unknown among the natives until the advent of Europeans, since when the disease had developed without any blood-admixture of the two races. It would, therefore, seem as though some specific germ was transported from place to place, and, having once obtained a foothold, remained to work its terrible results.

He thought the disease was much more curable than in former times. We constantly saw evidences in the post-mortem room of cavities that had healed over, in some cases finding the crustaceous remainders, the *débris* that had undergone chalky transformation, and any one whose professional experience extended back over a number of years could

undoubtedly recall cases of unquestionable phthisis that either entirely recovered, or, after living a number of years, died of some intercurrent complication. So far as treatment was concerned, he thought that putting aside the intrapulmonary injections, which could have only very limited application: that was to say, an application confined to those cases where the phthisis was limited in the amount of lung tissue involved, or in the case of cavities where there was but one, for the reason that we could not follow up a diffuse phthisis by a multiplicity of injections in widely separated portions of the lung: the treatment had to lie in the direction of the improvement of the nutrition in every way possible, and it seemed to him that a systematic study of the methods of improving the nutrition would cover pretty much the whole treatment of the disease. He did not think we had any specific remedy or treatment.

DR. S. J. MCNETT said that he had consulted the principal American and many German authorities to ascertain if they said anything about therapeutic resorts in the treatment of the disease in children, but had found that they all passed the subject over with the simple statement that the indications were the same as in adults. In fact, there seemed to be nothing peculiar in the indications for the treatment of the disease in children. Loomis probably had given more attention to the general subject of health resorts and the general climatic treatment than any other American author. He advanced the well-known rules with regard to sending away patients with this disease and added that the same general indications should be observed in regard to children born of phthisical or decrepit parents. Change of climate and surroundings was often of the greatest importance to them. He knew of no such powerful agent in arresting phthisical tendencies in childhood as systematic physical exercise in the open air. This physical training should be begun in infancy and continued to adult life. All the influences that tended to the development of hyperemia of the bronchial tubes, including impure air, should be avoided. Climate, more than anything else, in his opinion, had a controlling influence over the development of phthisis, except when the disease was tubercular. We know of no locality, however, that exercised an absolute curative effect, or where a person was absolutely free from danger of contracting the trouble; although it was formerly supposed that altitude exercised this power, it was now proved to the contrary, immunity being due only to the absence of the organic germs. Tubercular phthisis was not, as a rule, benefited by the change, and these patients did better in their own homes than anywhere else, but, in cases of the fibrous variety, high altitudes, such as Colorado or the different resorts in the Rocky Mountain range, appeared to be peculiarly beneficial. In the catarrhal form great care should be had when recommending a change of air. High altitudes were apt to prove rather a detriment than an advantage to such cases, owing to the liability they labored under of having attacks of hemorrhage. He did not think it was ever necessary to send patients out of our own country as we could find every variety of climate within its boundaries. In reply to a per-

sonal question, Dr. Loomis had said that he knew of no locality that seemed to have such a beneficial effect upon children with this complaint as the Adirondacks. Coates called attention to the fact that in persons whose respiratory muscles were weak phthisis was apt to be developed. This view was supported by the fact that persons living in high altitudes, where the air was quite rare, and where, consequently, greater respiratory exertion was necessary, seldom showed signs of succumbing to phthisis.

If phthisis could be shown to originate in imperfect expansion of the lungs, this fact would, in its turn, support the theory of a specific virus as an ultimate cause; because if the air stagnated, the germ would have the opportunity to remain in the lung and develop. Koch had found that the bacillus was of slow development at first, so that the absence of positive signs during a considerable period of its development was not at all remarkable.

Dr. F. R. STURGES did not consider syphilitic phthisis a common affection. It was to be distinguished from the phthisis of tubercular origin by the absence of emaciation and hectic. There was usually some impediment to the respiration, and perhaps slight pain. The cough, if present, was slight. If the infiltration was diffuse it was disseminated through the lower and middle thirds of the lung. Given diffused dulness in the lower third of the lung in any case without emaciation or fever, and with slight cough, he would suspect syphilis as a cause. If the affection were circumscribed a cavity might be formed which would contain either some pus or a mucilaginous tenacious matter, such as is found in gummatous infiltrations elsewhere. Hemoptysis rarely occurred, and under treatment the lesion healed; a cicatrix remained, and of course respiration was absent in that part of the lung. The speaker remembered a case in Charity Hospital which had hemiplegia, together with a tubercular crustaceous syphilide of the skin. The patient took five hundred grains of potassium iodide daily, under which treatment he improved and the hemiplegia disappeared. The dose was then diminished to three hundred grains per diem, when an attack of dyspnea occurred without expectoration, cough, or fever. There was no elevation of temperature, but physical examination showed consolidation in the middle third of one lung. The chlorides were not absent from the urine. The patient resumed the use of the five hundred grains of the iodide, and in three days the lung had cleared up. In children, pulmonary syphilis was usually diffused and not circumscribed. He had not found this syphilitic affection of common occurrence considering the great number of adults who had had syphilis; indeed, he believed that a large proportion of male adults had syphilis at some period of their lives. The ratio of the hereditary cases was small as compared with that of the acquired disease. The speaker did not consider that the resolution of a given lesion under the use of the mixed treatment was any proof of a syphilitic origin, as both mercury and iodide of potassium had the property of causing absorption of infiltration from whatever cause, as witness the use of large doses of calomel in pneumonias of non-syphilitic origin.

(To be continued.)

## Recent Literature.

*A System of Practical Medicine.* By American Authors. Edited by WILLIAM PEPPER, M.D., LL.D., assisted by LOUIS STARR, M.D. Vol. I., Pathology and General Diseases. Philadelphia: Lea Brothers & Co. 1887.

This work, which we understand it is proposed shall consist of three volumes, "has been undertaken," the editor's preface tells us, "in the belief that by obtaining the coöperation of a considerable number of physicians of acknowledged authority, who should treat subjects selected by themselves, there could be secured an amount of practical information and teaching not otherwise accessible." It was determined to restrict the selection of authors to those of this country because "it was felt that the proper time had arrived for the presentation of the whole field of medicine as it is actually taught and practised by its best representatives in America."

The chief purpose of those collaborating for the production of the work has been, it is announced, to furnish a concise and thoroughly practical system of medicine. Bibliographical lists, references, discussions of theoretical views or of controverted questions, and even illustrations have been curtailed as far as possible, in order not to defeat this object. The classification and nomenclature adopted are those recommended by the Royal College of Physicians of England and by the American Medical Association.

Under General Pathology and Sanitary Science, Prof. R. H. Fitz deals with general morbid processes, in nearly one hundred pages, which reflect the work and the views of the German pathologists; and Drs. Henry Hartsorne, J. S. Billings, and Mr. George E. Waring follow in much shorter articles upon general etiology, medical diagnosis and prognosis, hygiene, and drainage and sewerage in their hygienic relations.

Under General Diseases a variety of writers of more or less national reputation deal with infectious and contagious diseases—the old "zymotic" class. It would be impossible to attempt an analysis of any number of these articles which together occupy 800 octavo pages, and where there is so much that is good it is almost invidious to distinguish one or two. But we think Dr. J. H. Hutchinson's article on typhoid fever, which occupies one eighth of the whole of this portion of the volume, may fairly be selected for especial praise. The editor, Dr. William Pepper, furnishes an elaborate article on Relapsing Fever, having for its domestic inspiration an epidemic which presented itself in Philadelphia during the years 1869-70, when the writer had an opportunity of observing two hundred cases in the wards of the Philadelphia Hospital, but the article deals mainly with the observations of foreign authorities, as must necessarily be the case in regard to an affection which is fortunately an exotic, and a rare one at that, in this country.

This work is designed for the full grown practitioner, and this volume will unquestionably prove of value to such. The rest of the work will be awaited with interest.

# Medical and Surgical Journal.

THURSDAY, APRIL 23, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by CUPPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM AND COMPANY.

283 WASHINGTON STREET, BOSTON, MASS.

## THE CONTAGIOUSNESS OF SCARLET FEVER.

THE melancholy instance, which lately came to our notice, of a physician in a neighboring city, who, according to a fair presumption, carried the infection of scarlatina from his private clientele in town to a parturient patient in the country, from which the latter died in one week after confinement, may serve to put physicians generally on their guard against the danger of being carriers of contagion. It may be said that this result is very unlikely to happen, and there may be physicians who will rise to protest *they* have never had any such experiences! Happy if after carefully reviewing the memories of a long practice they can say this! Certain it is that one such event in a lifetime would be a responsibility too great! And puerperal patients are said to be especially susceptible to the scarlatinous poison.

That scarlatina is an eminently contagious disease no one disputes, and it is a hardly less disputable fact that unaffected individuals who have been in contact with, or in the presence of, persons sick with scarlet fever may communicate the disease through the medium of their clothing. Thomas relates a case in which a nurse, coming directly from a scarlatinous patient, gave the disease to a child who had almost recovered from tracheotomy. Sims also reports instances in which midwives have communicated the disease to lying-in women. In a case mentioned by Palante, a mother communicated the disease to her children, notwithstanding her short sojourn in the infected dwelling and her immediate journey home. Pyle mentions a healthy female teacher who imparted the disease to certain members of her family by the dress which she had worn while nursing a scarlatinous patient. Michel saw a family taken sick upon the return of the father from an infected dwelling, after a seven hours' journey. In the epidemic near Eidsvold in Norway, observed by Thoresen, the intense cold of winter prevented the children from leaving the houses, and the majority of infections (in twenty-four places) could only have taken place through the medium of

healthy individuals. Zengerie states that a healthy woman, after a visit to a person sick with scarlet fever, communicated the disease to her daughter, who was the first patient affected in the whole city.

Similar examples of the transportation of contagion from infected houses by healthy individuals might be multiplied; they will be found in any special treatise on scarlet fever.

The duty imposed on medical practitioners is an imperative one, and consists in the adoption of the same precautions to thoroughly disinfect the person from the virus of scarlatina, when exposure has been necessitated, that would be taken in the event of exposure to the contagium of small-pox, of which the physician would not willingly be the bearer to his patients.

Sulphur fumigations do not constitute an agreeable pastime; the eyes, nostrils, throat, and lungs resent the intrusion of the bactericide vapor, and many persons find it impossible to submit to the ordeal a sufficient length of time to ensure thorough disinfection. It is more than doubtful if fumigation with burning coffee, so often resorted to by physicians for the same purpose, is to be relied on.

On the whole, the following method of disinfection is to be recommended as practical and as giving the physician the minimum of trouble. The clothing worn during attendance on scarlet-fever patients should not be worn while ordinary visits are being made, and is not to be regarded as safe for common use till it has been thoroughly exposed in a close room to the fumes of burning sulphur. A change of outside clothing must, therefore, be made after every visit to a focus of infection.

The hands and exposed parts of the body may be disinfected by washing them in weak solutions (one part to 2,000) of corrosive sublimate, or of Condy's liquor potassie permanganatis diluted. As far as possible, there should be a stated hour each day for visiting scarlatinous patients, and when called to confinement cases unusual pains should be taken to destroy all virus which may possibly cling to the person. Prof. Léon LeFort recommends washing the hands in spirits of camphor; Van Swieten's solution may be subsequently used. Particular attention should be given to cleansing the nails. The skin of the face, the hair, and beard are not injured by the free application to these parts of liquor Van Swieten, or solutions of camphor, chloral, etc.

The Massachusetts Board of Health, Lunacy, and Charity has just issued a circular on Scarlet Fever. It emphasizes the fact of the contagiousness of this affection and insists on measures necessary for the prompt eradication of the disease when it appears in a community. The first principle of treatment is isolation: the patient must, as far as possible, be kept by himself, in a room separated from the rest of the house. The sick-room should be thoroughly

ventilated. Carpets, upholstered furniture, window-hangings, etc., which cannot readily be destroyed or disinfected, should be removed from the room. The discharges from the throat, nose, and mouth of the patient must be put in a vessel containing a strong solution of some disinfectant. Pieces of soft cloth may be used instead of pocket handkerchiefs and then at once burned. Cleansing gargles for the mouth should frequently be used, such as chlorinated soda or permanganate of potassium. Carbolic acid or bichloride of mercury may be added as a disinfectant to the slops and to the water in which the patient has washed or bathed, before throwing it out. If cosmoline, or sweet oil with a couple of grains of camphor to the ounce, is used for anointing the skin, the scales of epidermis (the principal seat of the contagion) are prevented to a considerable degree from escaping freely into the air; a warm bath daily is also useful for the same purpose. The bedclothes, towels, etc., when diseased, should be placed in a hot disinfectant solution (five ounces of sulphate of zinc and two ounces of common salt to a gallon of water) and boiled for a couple of hours.

Attendants on the sick should be as few as possible, and should not communicate with other persons any more than can be helped. Clothes used in the sick-room should be boiled before being used elsewhere.

After recovery the patient should not mingle with other persons, use lounges, carriages, public rooms, etc., until all roughness of the skin has disappeared, and until he has taken warm baths for several days.

Such are some of the stringent measures adopted by our State Board of Health and recommended to all local boards, and the general statutes of 1884 enjoin definite and specific prophylactic requirements of all physicians in relation to the disease. These sanitary rules are dictated alike by experience and enlightened views as to the causation of epidemics.

#### THE AMERICAN MEDICAL ASSOCIATION AT NEW ORLEANS.

THE American Medical Association will hold its thirty-sixth annual meeting at New Orleans, April 28th to May 1st. The date is a little earlier than usual, on account of the Southern latitude, which already threatens rapidly approaching hot weather. It is now sixteen years since New Orleans was selected for the place of meeting of the Association—years which have brought many changes at the North, but even more at the South.

Many members will undoubtedly find the distance and the expense of time and money impediments in the way of attendance. On the other hand, others will be tempted by the many attractions of the

Southern metropolis at this season, to which the International Exhibition is this year added, to make the necessary sacrifices.

Some important questions of organization, of nomination of officers, of future management of the Association's Journal are likely to come up at this meeting, and it would be desirable that different sections of the country should suitably be represented in the discussions and votes.

The facilities offered by the railway companies for reaching New Orleans from New England and other points have been duly announced in these pages.

#### ANNUAL REPORT OF THE NEW YORK STATE BOARD OF HEALTH.

THE annual report of the New York State Board of Health has just been presented to the Senate at Albany, and from its statistics it appears that during the last three quarters of the year 1884 there were reported to its bureau 56,353 deaths from all causes. Of these, 2,685 were from diphtheria, which has prevailed to a considerable extent in nearly every part of the State; and cerebro-spinal fever, associated with faulty house-drainage, has also shown itself in scattered districts in almost all sections, with a mortality record of 287. Malarial fevers caused 800 deaths, and erysipelas, 209; while there were none from small-pox. Eight hundred and sixty-four fatal cases of typhoid fever were reported, the larger proportion of them occurring in villages and rural districts, and 7,386 from diarrheal diseases.

The Secretary, Dr. Carroll, expresses the opinion that nine tenths of the wells in villages are impregnated with sewage, and that an index to the potential ravages of imported cholera in any given locality may be found in the extent of the endemic presence of typhoid fever and diarrhea; so that any measures adopted for the purpose of repelling the exotic pestilence will be of service in preventing these affections also. Of course, in the face of a possible visitation of Asiatic cholera, the report urges the importance of the energetic and conscientious performance of their duties by local health boards and of the hearty coöperation of town and county authorities with them; the prompt removal of all sources of pollution by decomposing organic filth, and the preservation of the purity of water, soil, and air in general, affording the best chance of immunity from either domestic or imported epidemics.

In reference to malarial affections, the report states that it is a fact placed beyond conjecture or argument that thorough soil-drainage will abate them. Apart from natural marshlands, artificial malarious influences have been created in many districts by the injudicious action of local authorities or private land-owners in obstructing the drain-

age-channels of watercourses, and thus inducing soil-saturation where nature had provided healthful conditions. The influence of defective school hygiene is also commended to the careful consideration of health boards as a matter which concerns the welfare not only of the present, but of future, generations.

#### MEDICAL NOTES.

—A *bon mot* credited to the late Thomas Gold Appleton, in the volume of his memoirs just published, was made to a friend who advised him to consult an aurist for an increasing difficulty of hearing in his later years. "It may be only wax in your ears," said the friend. "Ah, my dear," he replied, "I fear it is not wax but wane."

—The first session of the French Surgical Congress was held in Paris from April 6th to 12th, and passed off in the most satisfactory manner. We are in receipt of a synopsis of the papers presented, which suggests an advantageous imitation by other similar assemblages.

—Three cases of small-pox have been found in Boston lately. One was traced to a sleeping-car, one occurred in an immigrant, and the origin of the third could not be satisfactorily accounted for. The Board of Health has made prompt arrangements for the vaccination of all who apply. The immunity of this city and State from small-pox for the past eleven years offers a very remarkable example of the results of isolation and vaccination, but it emphasizes only the more strongly the importance of protecting the predisposed element in the population which is constantly renewing itself.

—General Grant was able from his past military experience "to put himself in the place" of his medical attendants to good purpose. His reported remark to his physicians savors of true wisdom: "The doctors outside, I am informed, are writing about my case and talking about it, and some of them seem to think they know more about it than you gentlemen do, but it is like a time of war when the men at home think they know more about it and how to do it than the generals who are in the field fighting."

—The *London Medical Times* considers the following the most unfortunate *lebens edam* which has come under its observation for a long time. The hero of the young lady novelist has succeeded with great difficulty in saving the heroine from falling down the precipitous side of a mountain on which they have lost their way. The heroine has fainted and is apparently lifeless. But to his intense delight the gentleman discovers that the heart still beats "by the pulse in her femoral artery."

—The trustees of the Peabody Fund, in London, announce that when the buildings in course of erection are completed, they will have spent the whole of their capital. Up to the end of last year they had provided for the artisan and laboring poor of London 10,144 rooms, occupied by 18,453 persons. The average weekly earnings of the head of each family in residence at the close of the year was £1 3s. 8½d. The average rent of each dwelling was 4s. 8¾d. per week, and of each room 2s. 1½d. The birth-rate for the year reached 44.60 per 1,000, which is 10.93 per 1,000 above that of all London for the same period. The death-rate, including the deaths of those inhabitants of the buildings who were removed to hospitals, was 19.10 per 1,000, which is 1.21 per 1,000 less than in London. The infant mortality was 138.69 in each 1,000 births, or 13.69 below that of London.

—We learn from the *Maryland Medical Journal* that among the most distinguished and successful female practitioners in London are Dr. Garret-Anderson, a sister of the wife of the late Professor Fawcett, and Dr. Arabella Kenealy, a daughter of the late Dr. Kenealy, of Tichborne litigation fame.

#### PHILADELPHIA.

—The past few weeks have been quite eventful in medical circles. The Jefferson Medical College held its fifty-eighth annual commencement on the 2d inst., at noon, graduating 176 candidates for the degree of M.D. Upon this occasion also the honorary degree of LL.D., was conferred upon Dr. Austin Flint, Jr., of New York. The Medico-Chirurgical College held its commencement on the same day, in the evening, graduating a class of five. The Medical Department of the University of Pennsylvania will hold its one hundred and seventeenth annual commencement on the first of May. It is said that the graduating class this year is a comparatively small one. The vacancy created by the resignation of Professor Mallet from the Jefferson Faculty has not yet been filled, but it is loudly whispered that, of the eight or ten who have been named for the position, the favorite candidate is Dr. J. W. Holland, of Louisville, Kentucky, who was the orator of the Alumni Association this year, and delivered a charming address two weeks ago in that capacity, taking for his subject "Our personal equations." He is a graduate of Jefferson College of 1868, and, it is said, had taught medical chemistry for ten or twelve years before taking his present position in the Louisville school. There is a strong feeling in the Faculty against the selection of a pure chemist, one who is not, at the same time, acquainted by actual experience with the problems of applied chemistry as they appear in the practice of medicine. At present it looks as if Professor Holland were to be the coming man.

—The vacancy in the Faculty of the Medical Department of the University caused by the resignation of Prof. Harrison Allen, from the chair of Physiology, will not be filled for the present, and the trustees have appointed Dr. E. T. Reichert to lecture temporarily upon that subject. Permission has been obtained for the erection, in connection with the newly formed Veterinary Department, of a building containing an amphitheatre and stalls for sick animals.

—The College of Physicians (not a medical school but a medical society) has finally secured sufficient funds to place a third story upon the well-known structure at Thirteenth and Locust Streets. The work will begin next month. The improvements are estimated to cost nearly thirty thousand dollars, most of which was subscribed by Fellows of the College. The very rapid growth of the library and the necessity for providing increased accommodation for the valuable Mütter Museum has led to this step.

—The Annual Conversazione (the first of the series) of the College of Physicians was held on the 16th inst., and was a signal success. A number of distinguished guests were present from New York, Washington, and elsewhere, as well as from this city. The entertainment comprised a microscopic display, a lantern exhibition, a demonstration of the effects of snake-poison upon the tissues of animals; the whole concluding with a social entertainment and a supper.

—The Semi-annual Conversational Meeting of the Pathological Society was held on the 17th inst., when Major George M. Sternberg, M.D., of Johns Hopkins University, delivered a lecture upon "Micrococci," which was followed by a supper at the Social Art Club. Among the events of the week we would also mention particularly the meeting of the Medical Jurisprudence Society on the 13th inst., when Clark Bell, Esq., of New York, gave an able exposition of the laws relating to the insane who commit crime, in his paper entitled "Shall we hang the insane who commit homicide? A criticism on the execution of Dr. Beach." A spirited discussion followed the reading of the essay, and some needed reforms in the practice of our courts of law were strongly urged.

—Dr. Frank Woodbury has been elected to the chair of Therapeutics, Materia Medica, and Clinical Medicine, in the Medico-Chirurgical College of Philadelphia.

—The County Medical Society has been quite active of late. Through its Committee on Hygiene and the Relations of the Profession to the Public it has at length taken steps toward the prosecution of illegal practitioners of medicine, with which intent it has chosen a legal adviser, and has instituted a series of public lectures upon hygienic topics. Dr. E. O. Shakespeare discoursed on Cholera; Colonel

Ludlow, chief engineer of the Water Department, delivered a lecture criticising the present water-supply and recommending certain improvements, and Dr. A. L. Gihon, United States Navy, gave the third lecture of the series last Saturday evening (18th inst.) upon "Sanitary ignorance among the high and low." This course of lectures is attracting large audiences and is calculated to do much good. At the same time the City Board of Health is keeping up interest in matters relating to the public health by its efforts to improve the sanitary condition of the dark places of the city. Twenty-five inspectors are now making house-to-house visitation and their progress is daily published by the newspapers, which colliken their reports with many interesting and suggestive incidents of the work.

—The public lectures on Nursing, by Miss Fisher, at Blockley, are still in progress, and have been nearly as popular as the preceding course upon Accidents and Emergencies, attendance upon which was quite the mode among the ladies.

—Although our City Councils reprimanded the chief engineer for publicly maligning the present water-supply, in the lecture before the County Medical Society above referred to, he has ably defended himself and has shown by analyses that it would be almost impossible to speak of it in sufficiently uncomplimentary terms. In this connection, it is worth noting that the Legislature has just passed an act creating a loan of three millions of dollars for the improvement of the water-supply of Philadelphia, a bill which it is hoped will be promptly signed by the Governor. The Legislature is also considering a bill creating a State Board of Health with a strong presumption in favor of its final adoption this session, as it has already passed the Senate.

## Correspondence.

### A CONSIDERATION OF EXTRAVAGANCE IN THE USE OF ETHER.

Is an editorial<sup>1</sup> entitled "Extravagance in the use of ether," two statements occur: "The great bulk of the drug usually required is a bar to its universal adoption." "The amount which a man in civil practice must carry with him is quite a burden to one accustomed to the small amount of chloroform needed to obtain the same result." These sentences, with many similar occurring in Dr. Burrell's paper,<sup>2</sup> and the discussion upon it are not what one would expect to find emanating from the cradle of anaesthesia by ether. A general ignorance seems to pervade the professional mind on the subject of ether inhalation. Men who have employed the drug during years of practice are unconscious of the results which by proper use can be attained. They submit meekly to the statement of the chloroformists that the enormous sacrifices of time, coupled with the uncertainty in producing anaesthesia are not compensated for by the extra safety, which in reality is only problematical. They hear it urged that accidents occurring can easily be

<sup>1</sup> Boston Medical and Surgical Journal, February 4, 1885.

<sup>2</sup> Boston Medical and Surgical Journal, January 24, 1885.

foreseen, and are generally traceable to some error in judgment, or want of care in administration, while they tacitly agree that chloroform is more agreeable to the patient. These assertions, with the exception of the last, which for the moment I concede, can be met by a general denial. The time necessary to produce anesthesia by ether, properly administered, in the most approved manner, is as short as that required for chloroform. The extra safety is beyond argument; statistics, though unsatisfactory, are convincing on this point. Accidents occurring are not due in many cases to any want of care or foresight. Fatalities in the hands of Snow, Clover, and Simpson, with other eminent anesthetists, disprove the assertion. These points, with others in controversy, I endeavored to contrast in a brief article<sup>3</sup> on the subject, illustrating the fact that fatalities in chloroform administration are often unprececeded by any warning. Dr. Burrell gives eleven propositions, which he thinks will be acceptable to all; and, with the exception of the ninth, in which I would reverse the order of premonition, they may be taken for granted. Amongst the questions on which there might be a difference of opinion is "the comparative values of a sponge, towels, and inhalers." This is really the point of importance in the controversy. While Dr. Burrell's proposition that the best medium of administration is "one in which ether can be given in a condensed form, or largely mixed with air," is practically true, the essence of effective anesthesia by this drug is its administration in as concentrated a form as possible. This can only be accomplished by a properly constructed apparatus or inhaler; and there can be no comparison between such an instrument and the sponge, cone, or towels. Such a statement only requires practical demonstration to convince the most incredulous; and yet, not one gentleman who joined in the discussion seems to have had any impression made on him, except Dr. Bradford, who had seen Clover administer gas and ether effectively and without a struggle. The proposition that the less ether used during the operation the more rapid will be recovery and successful the result is incontestable. Stress should also be laid upon the necessity of briefly describing to every adult what the primary sensations of an anesthetic are. Absolute quiet in the surroundings is of great importance. I have frequently seen violent and painful struggling during the semi-conscious stage follow some loud remark or laugh from some one present. I will premise my observation by assuming the position that the only rational method of giving ether is by a suitable inhaler. Most anesthetists aim at certainty and safety in effect, with power to indefinitely prolong the anaesthesia; rapidity of action and economy in the quantity used. The only way to meet these conditions is by mechanical apparatus. No towel, or mackin, or sponge, with newspaper cone added, can do it. There is no certainty of producing anaesthesia; the time occupied is relatively to the operation often much greater. The quantity of ether used is out of all proportion to the necessity of the case; and, in the words of the leading article, its high diffusive power will affect the olfactory nerves of a neighboring practitioner. The perfect method of giving ether is that where nitrous oxide gas is first administered; but as this is only obtainable in cities, and then not always with convenience, some of the main disadvantages, where ether is used alone, must be met and overcome. As I have elsewhere stated, the requisites for an efficient ether inhaler are: simplicity in construction, compactness, and portability; the delivery of the greatest amount of vapor, with the least compatible quantity of atmospheric air. Clover's small inhaler and Ormsby's pocket inhaler are equally effective; but the simplicity, compactness, and

portability of the latter render it much superior. Some object to the inhalation of concentrated ether vapor, where the same air is continually respired, on the ground that the anesthesia is in reality modified asphyxia. I have on many occasions maintained complete unconsciousness for more than an hour, and cannot remember even an unpleasant symptom which was traceable to this cause. Space does not permit a detailed description of Ormsby's inhaler. The principal points are: a flexible metallic face-piece; the base of which is fitted with a rubber air-tube to assure accurate approximation; a wire-net cone containing the sponge for ether; and a stout rubber bag enveloping the cone, into, and from, which the patient breathes through the sponge. The apparatus can be taken to pieces in a moment, and its construction will admit of the most thorough cleansing. Dr. Burrell objects to a sponge in any form; but the small piece required for this instrument will enable him to procure a new one after suspicious cases. The inhaler does not easily get out of order, and parts can be readily replaced. The admission of air is regulated by a revolving cap over an air-tube, which, as it turns, covers or exposes a slot. This is under the control of the anesthetist, and is not open to Dr. Burrell's objection (with which I most fully concur) against "automatic valves." The instrument which will be most successful in the hands of an operator is that to which he has been accustomed; yet, while I am prepared to admit that excellent and indeed equal results can be shown for other inhalers, I believe that this has many points of superiority. Having administered ether by its means considerably over one thousand times, with patients of all ages, and also had complete anaesthesia produced with it on myself on three occasions, I think I can point out how the best results can be most readily obtained. As noted in the JOURNAL, there are certain classes of patients, who with any management will always give trouble, included in which are the so-called "hysterical women," hard drinkers, and young children. In the first two, I believe that, after a slight degree of unconsciousness is produced, it will generally be necessary, and always advisable, to use restraining force; and I agree with the author that, where young children are the subjects, it is more humane to do so. I will suppose that the patient to be anesthetized is an adult, and that the case presents no marked peculiarity. Having taken the ordinary precautions prior to, and at, the time of administering an anesthetic, the inhaler is prepared for use by inflating the air-tube attached to the face-piece and replacing the sponge, first thoroughly expressing the water in which it has been soaking. Telling the patient that there is no ether in the inhaler, place it over the mouth and nose, and moulding it to fit, briefly describe the sensations he is about to feel. I insist on his keeping the mouth shut, and breathing only through the nose, taking slow and easy inspirations, and avoiding, as far as possible, using the full capacity of the chest. From personal experience I have found this the only way to obviate the very distressing cough and awful sense of suffocation that is the greatest disadvantage with ether inhalation. As we ordinarily see, the patient is urged to take deep inspirations, and the irritant action of the vapor, as it passes over the laryngeal mucous membrane at once excites spasms, the effect being increased by its concentration when an inhaler is used. Having gone through these preliminaries, remove the instrument and pour one ounce of ether on the sponge, replace it with the air-slot wide open. An assistant should secure the wrists of the patient, not pinning them down, as Dr. Derby's "medical spectator" would do, but having sufficient control to prevent the net or rubber bag of the apparatus being torn. In about twenty-five or thirty seconds cut off half the air-supply, and shortly after close the slot, so that the same ether-charged air is breathed

and rebreathed. At this stage, the patient has usually become so far unconscious as not to recollect events, and so any struggling or remarks may be treated as the acts of an irresponsible being. Coincident with the advent of anesthesia, the rubber bag becomes fully distended on expiration, rising and falling, slowly and regularly. The eye of the administrator should be fixed on the chest, the fifth finger of either hand can be kept on the temporal artery; but long before serious cardiac symptoms appear the irregularity in respiration will have attracted attention. If more ether is required, it should be added in quantities of four drachms, and when anesthesia is to be prolonged beyond half an hour, it is advisable to remove the sponge, and squeeze it dry before replacing, repeating the process every thirty minutes as it becomes saturated by condensation of the vapor exhaled by the lungs. The average time required to produce anesthesia is about two minutes. The average quantity of ether employed one ounce, while two ounces will frequently maintain perfect insensibility for twenty-five or thirty minutes. I do not know of any method that surpasses these results, and there are certainly very few that at all equal them. I prefer to anesthetize with the patient on the back; for many reasons it is most convenient. A small towel or napkin, resting under the right hand of the anesthetist, is necessary to remove any mucus which, coming to the orifice of the mouth, may be expectorated into the inhaler. The head, neck, and throat should be on a gentle incline, so as to keep the thorax straight: this is best attained by means of a

pillow under the shoulders. Without dwelling on the ordinary details which must be observed where ether is used, I would lay great stress on the following points:—

(1) Impress the patient that he is to respire gently, breathing only through the nose.

(2) Always measure the ether used, and avoid pouring the fluid haphazard on the sponge.

(3) Remove the sponge at intervals of thirty minutes, and express the accumulated fluid.

Having entered at some length into the question of rapidity and certainty of anesthesia, and pointed out the effects that can be produced, I wish to add a word on the subject of "bulk," which the editorial dwells on as a prominent disadvantage. I had recently a case made for the inhaler; it is of leather, just large enough to contain the instrument. It represents, when closed, a flattened, conoid figure, opening at the base with a lid. The measurements roughly are: greatest length, 7 1-2 inches, breadth at base, 5 1-2 inches, at apex, 3 1-2 inches, diameter at base, 3 3-4 inches, at apex, 2 inches. In addition to the inhaler, it contains an ounce measure, a spare rubber face-piece, and a reservoir holding twelve ounces of ether. These are merely rough models, which I hope soon to give to the profession in a finished form. Meanwhile, I would suggest that in the face of the foregoing figures and facts some modification can be made in the editorial strictures. Very respectfully yours,

JAMES H. PARKINSON.  
SACRAMENTO, California.

## REPORTED MORTALITY FOR THE WEEK ENDING APRIL 11, 1885.

93 Massachusetts towns . . . . .	—	99	22	7.07	17.17	3.03	1.01	—

Deaths reported 2,170; under five years of age 755; principal infectious diseases (small-pox, measles, diphtheria and croup, erysipelas, fever, and diarrheal diseases) 312, lung diseases 491, consumption 233, diphtheria and croup 113, scarlet fever 44, diarrheal diseases 40, typhoid fever 19, malarial fevers 17, cerebro-spinal meningitis 16, puerperal fever 10, whooping-cough nine, erysipelas seven. From typhoid fever, Philadelphia six, Baltimore four, Boston three, Buffalo two, District of Columbia, Charleston, Worcester, and Fall River one each. From malarial fevers, New York nine, Baltimore and District of Columbia three each, Philadelphia and Springfield one each. From cerebro-spinal meningitis, Philadelphia five, Buffalo four, New York, District of Columbia, Lowell, Worcester, Fall River, Malden, and Fitchburg one each. From puerperal fever, Philadelphia four, Boston two, Buffalo, Lowell, Worcester, and Springfield one each. From whooping-cough, New York six, Baltimore, Lawrence, and Holyoke one each. From erysipelas, New York and Lowell two each, Philadelphia, Boston, and Worcester one each.

Cases reported in Boston: measles 85, scarlet fever 51, diphtheria 34, and typhoid fever seven.

In 114 cities and towns of Massachusetts, with an estimated population of 1,551,575 (estimated population of the State 1,955,104), the total death-rate for the week was 21.77, against 20.80 and 19.09 for the two preceding weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,906,446, for the week ending March 28th the death-rate was 23.2. Deaths reported 3,267; infants under one year of age 974; acute diseases of the respiratory organs (London) 448, measles 176, whooping-cough 124, fever 37, diarrhoea 37, scarlet fever 31, small-pox (London 21, Sunderland two, Manchester and Newcastle one each) 25.

The death-rates ranged from 17.8 in Portsmouth to 41.9 in Cardiff; Birkenhead 24.3; Birmingham 19.4; Bradford 18.5; Leeds 23.0; Leicester 24.1; Liverpool 25.0; London 22.2; Manchester 31.2; Nottingham 20.2; Sheffield 21.3; Sunderland 40.4. In Edinburgh 18.9; Glasgow 30.0; Dublin 40.4.

The meteorological record for the week ending April 11th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending Saturday, Apr. 11, 1885.	Barometer.  Daily Mean.	Thermometer.				Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather.			Rainfall.  Duration, Hrs. & Min. Amount in Inches.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM APRIL 11, 1885, TO APRIL 17, 1885.

BROWN, HARVEY E., major\* and surgeon. Leave of absence extended two months. S. O. S., A. G. O., April 11, 1885.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE WEEK ENDED APRIL 11, 1885.

BALLHAUGH, P. H., surgeon. Chairman of Board for physical examination of candidates for appointment as assistant engineers, Revenue Marine Service, April 6, 1885.

VAN SANT, JOHN, surgeon. Chairman of Board for physical examination of officers of the Revenue Marine Service, April 11, 1885.

PURVIS, GEORGE, surgeon. Granted leave of absence for one week. April 6, 1885.

SPRING, G. W., surgeon. Member of Board for physical examination of candidates for appointment as assistant engineers, Revenue Marine Service, April 9, 1885.

GARDNER, JOHN, surgeon. To represent Service at annual meeting of American Medical Association, April 11, 1885.

GORDON, GEORGE, U. S. B., passed assistant surgeon. To proceed to Pascagoula, Miss., as inspector. April 8, 1885.

CHURCH, H. B., passed assistant surgeon. Member of Board for physical examination of officers of the Revenue Marine Service, April 11, 1885.

#### SOCIETY NOTICES.

STUTTGART DISTRICT MEDICAL SOCIETY. The annual meeting of the Society at the Hotel de Ville on Saturday, April 25, 1885, at 8 P.M. Paper, Dr. Robert T. Lohs will read a paper on "Some New Methods of Treating the Heart." Incidental Business. Report of Treasurer, Librarian, and the Committee on Special Meetings. Election of Officers. Supper after the meeting. Members are requested to notify the Secretary of any change of address. C. M. GELLEN, Secretary.

AMERICAN NEUROLOGICAL ASSOCIATION. — The eleventh annual meeting of the Association will be held in New York, E. Wednesday, June 17, 1885, and will continue three days.

#### MASSACHUSETTS MEDICAL SOCIETY.

It is proposed at the June meeting of this Society to give members of the Society an opportunity to put upon exhibition any new apparatus or instruments devised by themselves. Appliances previously shown at the Society meetings will not be admitted. Applications and communications should be addressed to J. W. ELLIOT, M.D., 75 Marlborough Street, or A. T. CABOT, M.D., 3 Marlborough Street.

Committee on Exhibit.

#### THE ASSOCIATION OF AMERICAN MEDICAL EDITORS. ANNUAL MEETING.

The annual meeting of the Association of American Medical Editors will be held in New Orleans, La., April 27th, at 8 P.M. in the Medical College Building. The annual address will be delivered by the President, Dr. Henry O. Marey, of Boston, Mass., on "The Legislative Establishment of Medical Examining Boards in America." Papers are expected from Dr. F. E. Daniel, Austin, Texas; Dr. F. S. Billings, Boston, Mass.; Dr. Richard J. Dunglison, Philadelphia, Pa.; Dr. John V. Shoemaker, Philadelphia, Pa.; Dr. L. Connor, Detroit, Mich.; and others. All members of the profession are cordially invited to be present and participate in the meeting, especially journalists and authors.

H. O. WALKER, M.D., Secretary.  
33 Lafayette Avenue, Detroit, Michigan.

Typhoid Fever and its Treatment. By James J. Leveik, M.D. (Reprint.)

Twenty-fourth Annual Report of the Cincinnati Hospital to the Mayor of Cincinnati for the Fiscal Year ending December 31, 1884.

Announcement of Newland's College of Midwifery and Lying-in Institute for 1885. St. Louis.

## Original Articles.

## THE PRINCIPLES OF SANITARY PLUMBING.]

BY J. PICKERING PUTNAM, ESQ., OF BOSTON.

THUS we see that with the long stack of pipe our ventilation has signally failed. We will now cut off half the bends and half the length both of soil and vent pipe, leaving a medium length of each of forty-five feet.

A discharge of the closets has lowered the seal to one and one-half inch. Four discharges have destroyed the seal.

At the last lecture we found it possible to break the seal by discharging only one of the closets at a time. But it required eight repetitions of the discharge to do this, and we shall accordingly omit the experiment to-night for want of time and because our subject extends over a wider field than before. Our next experiment will be with an ordinary one and one-fourth inch vent-pipe which is really the size of the trap under consideration. Omitting the tests with a medium length of soil and vent pipe which broke the seal of this trap in two discharges, and also the test with a single closet, we will shorten the ventilation-pipe to fifteen feet by cutting off the two-inch iron pipe and all its bends altogether. This gives us a shorter vent-pipe than we should ever be likely to encounter in practice. Hence, if the friction produced in this short length of pipe is enough to prevent the effectiveness of the vent, anything longer than this would certainly destroy its power. The soil-pipe is of medium length.

*Discharge of Z and J.* Four simultaneous discharges of the closets have destroyed the seal of our trap, fully vented with a new in the manner required by the law, showing our expensive venting to be utterly untrustworthy, even under the simplest conditions. In the experiments made for the City Board of Health the same results were obtained by the discharge of a single plunger-closet.

*Four-inch by four-inch Y.* We have, up to this time, used a four-inch by two-inch Y branch to connect our lead branch with the main soil-pipe. In our experiments for the Board of Health we were severely criticized by *The Sanitary Engineer* for using a four-inch by four-inch Y branch, which, we were told, would produce an action at least four times as powerful as the smaller branch. In order to test this we will connect our waste with a four-inch by four-inch branch immediately below the one we have been using, and repeat the last test under the new conditions. I would caution those of the audience who are seated nearest the trap to hold firmly to their seats, which have been tightly screwed to the floor in order to prevent them from being sucked bodily into the drains by the prodigious siphonage power of our four by four-inch branch.

*(Discharge of Z and J.)* We find no appreciable difference in the two Ys, and I think those gentlemen can now safely release their hold upon the furniture.

We have records of comparative tests made with two such Ys, made in exactly the same position on

the apparatus, showing a greater rather than a feebleness action produced by the smaller Y.

*Experiments with a Partially Clogged Vent-pipe.* When the mouth of the vent-pipe has been partially closed by gradual deposit of sediment, the supply of air through it is proportionally retarded, and it becomes less and less of a safeguard against siphonage. We have made a great many experiments in this field and found the resistance exactly proportioned to the size of the vent-pipe.

In the tests for the Board of Health we used a straight stack of pipes without any bends. The siphonic action was somewhat more severe in all the tests.

*Secondary Office of the Vent-pipe.* It remains now to examine the secondary office of the trap vent-pipe, namely, the aëration of the branch waste-pipes, promoting decomposition in them, and carrying off the gaseous products of such decomposition.

Some years ago, before it became customary to ventilate all the main lines of soil and waste pipe, as all sanitary engineers are agreed in recommending now, there accumulated in the upper part of the pipe-system large volumes of dangerous and corrosive gas generated by the decomposition of the heavy deposits in the large soil-pipes throughout their entire length. These gases, never liberated as they are now by a constant current of fresh air passing through the main pipes, sometimes formed in such large quantities as to eat through the metal and escape into the house. The water-flushing from the feeble pan-closets of that time was quite insufficient to purify the main-pipe lines, and serious difficulties arose.

Now, however, the case is very different. All our main pipes are thoroughly ventilated, and a far more liberal flushing is occasioned by the use of modern hopper-closets. This comparatively fresh air of the soil-pipe distributes itself by diffusion through the branch wastes, and gases can no longer collect to any harmful degree unless they are of unusual length and insufficiently flushed.

Consider the case of a short-branch waste-pipe leading from a well-constructed washbasin and connected with a well-ventilated soil-pipe.

Fresh air is constantly passing through the soil-pipe, carrying off the products of combustion as fast as they are formed. If the lavatory be frequently used and properly constructed the short-branch waste-pipe is scoured from end to end and kept very free from foul matter. Fresh air is diffused easily from the soil-pipe through this short branch as far up as to the trap. If the fixture is rarely used the last thin deposit of soap dries up on the sides of the pipe, and what little decomposition goes on then is inappreciable, and the products are removed by diffusion, or, if they are absorbed in the water of the trap, what could escape from its surface would, as we have seen, be absolutely infinitesimal and harmless. Not so if we ventilate this short-branch waste, as now required by law. A few days is sufficient to evaporate out all the water from the trap, and soil-pipe air may then enter the house freely. This is no careless assertion founded on theory. It is the result of a series of very careful experiments made by myself, and published in the

sanitary journals, and it is the experience of experts who have examined the working of the trap-vent law during the short period since its enforcement.

Consider next the long-branch wastes of lavatories. We will suppose the fixture to be a washbasin or bathtub used every day. If the outlet be properly constructed the discharge of the fixture will fill the pipe so full as completely to drive out the air that was in it and fill it with a volume of perfectly fresh air from the room. Every one has observed fresh air being sucked into the outlet of a lavatory, at the time of discharge, in volume sufficient to renew the air of the branch waste-pipe many times over, even with basins improperly constructed as they are.

We will suppose the fixture to be very seldom used, say not oftener than once a week or month, as in a spare room. The last charge of water passes off and the pipe dries up. I believe that what decomposition would then go on in pipes connected with a properly constructed lavatory would be utterly harmless; and more than this, I believe there is no case on record of harmful corrosion ever being found on such branch wastes. It certainly would not do to ventilate the trap of such a fixture left in periodical disuse. For evaporation would unseat its trap in its intervals of rest, and far greater damage would arise than could come from the unventilated pipe. Those who do not possess this degree of confidence have only to arrange their fixtures in such a way as to avoid long-branch wastes, and the difficulty will for them be avoided.

Consider now the question of branch wastes from kitchen and pantry sinks. Every one knows that grease and sediment from these fixtures will at once clog up in time any part of a trap not scoured by the water. We find the upper part of ordinary pot-traps always fouled with grease in such cases. The mouth of the vent-pipe taken from the top of such a trap also becomes similarly clogged, and it is probable that in whatever way the vent-pipe be attached to the trap of a sink it will surely become clogged and inoperative in time.

The only case in which trap ventilation can be recommended, as it seems to me, is in connection with certain kinds of water-closets. The consideration of this branch of my subject must be left for another time.

I find, therefore, no advantage whatever in trap ventilation, with the above possible exception. There are several disadvantages which, summed up briefly, are these: *First*, it destroys the seal by evaporation when ordinary S traps are used and when the vent-pipe is taken from the crown, as the law in some places requires. I find that if the vent-pipe be taken from some point six inches or more below the crown evaporation does not go on, or it goes on so slowly as to be harmless with traps holding a reasonably large body of water. With S traps, however, it is necessary to ventilate at the crown if they be used at all in order to prevent self-siphonage.

*Second*, The vent-pipe does not accomplish its objects, and hence affords a false sense of security.

*Third*, It increases the unscoured area of the trap, making it a cesspool. The ventilated S trap is used instead of a reservoir-trap by the advo-

cates of trap ventilation for the sake of avoiding an unscoured chamber. But in doing so they add a sediment chamber, which is not only greater in extent of surface, more easily fouled and less easily cleansed, than that in the pot-trap, but one which is far more dangerous, inasmuch as its fouling, even to a limited extent, involves the destruction of the whole system. This chamber is as certain to become inoperative after more or less use as is any reservoir or cesspool in a trap to become clogged with deposit. It is so placed and of such a form that it must inevitably receive splatterings from the filth-laden wastewater, without benefiting by its scour. I have found, by repeated test, that the water discharged

Fig. 4. Trap vent, clogged at the mouth.

from a washbasin with a large outlet and trap placed a foot or more below is thrown up over ten inches into the vent-flue at every discharge. Thus a very large sediment chamber is formed. The deposit of sediment may be rapid or slow, according to circumstances, in some cases requiring years to reduce the size of the vent-opening to the point of inefficiency. In others this will occur in a few days.

*Fourth*, It retards the outflow of the wastewater about thirty-three per cent. This is owing to the friction of the air-current entering with the water during the discharge.

*Fifth*, It renders the discharge noisy. The same air-suction which delays the water produces a disagreeable roar when the water discharges rapidly.

*Sixth*, It complicates the plumbing and adds to the danger of leakage through bad jointing and increased material.

*Seventh*, It aggravates the danger arising from capillary attraction; and, finally,

*Eighth*, It seriously increases the cost of plumbing, an increase which amounts to as much as from five to ten per cent. on the total cost of the plumbing in new work and indefinitely in old work in which the trap ventilation sometimes becomes by far the greatest part of the work to be done.

Fig. 5. Complexity with Insecurity.

Figs. 5 and 6 represent three fixtures plumbed by the two different methods, the first with, and the second without, trap ventilation. In the first drawing the overflow-passage and the house-side of the trap are ventilated as well as the sewer-side, and the loss of the water-seal through evaporation is

very rapid. This double trap ventilation is not common, but yet is occasionally carried into execution by some of our more radical enthusiasts for branch-waste venting.

Fig. 6. Simplicity with security.

In the second drawing "Sanitas" traps are used which require no ventilation to prevent siphonage.

A washbasin, having an outlet large enough to fill the waste-pipe and trap "full-bore," scours them and keeps them free from deposit.

The use of a urinal is rarely to be recommended. It is only introduced here for purposes of illustration.

**Second Method.** Let us now examine the second method of obtaining security against siphonage. This consists in the use of a large unventilated pot or reservoir trap. A small pot-trap will not resist siphonic action, but a large one will. Their power of resistance is exactly in proportion to their size. Nothing smaller than an eight-inch pot-trap, which I have here, can be relied upon in all cases. A six-inch pot-trap will sometimes be siphoned out by discharges occurring in common practice. A five-inch pot-trap siphons out much easier. An ordinary four-inch trap has very little resisting power unless its seal is unusually deep. Three-inch and two-inch traps are altogether useless.

We will test practically the action of siphonage on a four-inch pot-trap of the usual depth of seal.

**Discharge Z and J.** We see that three discharges are sufficient to break the seal of this trap. In our last lecture we found that either the Zane or the Jennings closet alone was able to destroy the seal in eight and six discharges respectively.

Thus we see that only the largest sizes of pot-traps are reliable. To be secure in all cases, if we use pot-traps, we are required to have them as much as six or eight inches in diameter, and constantly inspect them to see that they are free from deposit. Traps of this size are veritable cesspools and as such are to be avoided wherever it is possible. They are, moreover, expensive. A plumber's scale of charges for these traps is at the rate of one dollar for every inch in the diameter of the trap. Thus a five-inch, six-inch, and eight-inch pot-trap costs \$5, \$6, and \$8 respectively.

The pot-trap is, moreover, bulky and unscientific in construction. Its cleanout cap is faultily arranged at the top, where, if improperly adjusted, it will allow of the escape of sewer gas without warning. The cleanout cap of a trap should always be wholly or in part below the normal level of the standing water in order that if an unsound joint occur it will at once be detected by an escape of

water and the defect remedied. It is better to endanger the floors or plastering than the life or health of the owner.

To ensure tightness the plumber is obliged to screw the cap on so hard that the house-owner is rarely able to unscrew it for examination or cleansing. Hence the plumber has to be sent for. Ill-feeling is aroused and the plumber is referred to in terms often lacking in refinement and politeness.

Under the name "reservoir" traps I include all water-seal traps which are not self-scouring. It includes the old-fashioned D trap (Fig. 7), the Globe trap, and the Bottle trap (Fig. 8).

Fig. 7. D trap clogged.

Fig. 8. Bottle trap.

Of all the reservoir-traps, the common pot-trap, bad as it is, is the best, as being the simplest.

Balls, valves, and gates in traps add little or nothing to their power of resisting siphonage, and have no longer any value now that it is customary to ventilate the drain and soil pipes. They serve only as encumbrances and filth-collectors.

We come finally to the *third* method of obtaining security against sewer gas, of which Fig. 6 forms the general illustration. It is to give the trap such a form as to render it antisiphonic and self-cleansing at the same time.

#### ANTI-SIPHONIC TRAPS.

Let us first examine the action of fluids in traps when they are subjected to siphoning action and see if it is possible to construct a trap in such a manner as to accomplish these results. To better study the movement of the fluids we have had a number of S and pot-traps constructed wholly of glass.

We must make use of the natural forces at our command, the superior gravity and adhesive force of water over air, and construct our trap with reference to the laws governing these forces in the movement of the two fluids.

Examining first our pot-trap. Under a powerful siphonage air is driven through the water in the body of the trap in the manner shown in this drawing (Fig. 9). A quantity of water is projected out of the trap in advance of the air-column, as shown by the arrows. If the action were continued long enough all the water above the inlet-mouth, even in the largest pot-traps, would be expelled. It will be observed that part of the water is forcibly thrown up against the top of the body of the trap, whence it is deflected back in the form of spray in all directions. Part of the spray, however, falls across the outlet-mouth, and is sucked out. One of the prin-

principal reasons why the S trap is so easily siphoned out is that the curve at the top conducts the water directly into the outlet. Some form of reflecting surface should be used to throw the water back into the trap, and let the lighter air escape to supply the

Fig. 9. Movement of fluids in a pot-trap.

vacuum in the soil-pipe. Such a reflecting surface is found in the flat top of the pot-trap above the outlet-mouth. We will therefore retain this useful feature, but reject the objectionable one of the excess of sectional area in the body over that of the inlet and outlet arms, and we have our first modification, as shown in Fig. 10. The reflecting surface,

Fig. 10. First modification.

however, should not be arranged as here shown. The pocket increases the unscoured area of the trap. It is true it is no worse than the mouth of a ventilating pipe, which under the present law it is customary to put at this place. But it is just as certain that such a pocket will become clogged in time as it is that grease and filth will deposit a sediment on everything with which it comes in contact. The higher or deeper the pocket the more readily will the deposit be formed. A shallow pocket might be partially scoured by the force of the water projected upward against it by momentum. In this case a certain portion of each deposit of filth would be washed off by friction and the process of clogging would be somewhat retarded. But let the pocket be deep enough and there will then be parts which will be within the reach of the waste-water, but beyond its scouring effect. The spray thrown up by momentum will at this height have lost its power. The drops of dirty water will simply rise to their turning-point, deposit their filth, and trickle back again into the trap. The ventilating outlet forms exactly such a pocket. At a certain height above the crown of the trap the inner surface of this flue will receive the splatterings of the filth-laden waste-water, but never receive its scour. Hence the area of the vent-opening must infallibly continue to decrease in size more or less quickly, according to the usage of the fixture, until the opening is too contracted to be of any value in resisting the action of siphonage on the water-seal. More-

over, the cool ventilating draught helps to congeal the fatty vapors arising from hot waste-water in the trap and hastens clogging. We will, therefore, simply retain the reflecting surface but reject the pocket. Furthermore, we will slightly contract the inlet and outlet mouths at their junction with the body. This allows the air rushing through the body of the trap to pass through the water instead of driving it out before it. A very slight contraction is

Fig. 11. Second step. Partial contraction of inlet and outlet mouths and reduction of pocket.

sufficient. These two modifications make the second step in our improvement, and are shown in Fig. 11. A trap was constructed in this manner, and proved to be very much stronger in resisting siphonic action than an S trap of equal depth of seal.

Still our trap is very far from antisiphonic. Referring to our glass pot-trap, we shall see that the water projected violently upward from the surface, by the air-bubbles rushing through the standing water under the influence of siphonage, is obliged to pass twice by the mouth of the outlet-pipe, once before and once after reflection against the top, and that it is at these moments that it is sucked out and lost. That part of the spray which happens to be thrown farthest from the mouth of the outlet-pipe will be seen to fall back safely into the trap; but that which passes near this outlet, either in rising or after reflection, is drawn out by the concentrated and powerful suction at this point and wasted. And we find that one of the principal reasons why a large pot-trap resists siphonage longer than a small one is that in the large trap the spray has more space above the surface of the standing water than in the small one, so that a smaller proportion of the water thrown up by the rushing air-bubbles passes within the influence of the suction at the outlet-pipe. If our reflecting surface could be placed below instead of beyond the mouth of the outlet this loss could be avoided. Our next step

Fig. 12. Third step.

must, therefore, consist in so placing the reflecting surface. In Fig. 12 this has been accomplished, but in an awkward manner. Before this surface can come into service the level of the water must evidently be reduced to the level shown by the shading in the figure. Hence the perpendicular part of the body of the trap above the lower reflecting surface is not placed to advantage. Nevertheless, this trap will resist a very powerful siphonic action, even as it is. The two reflecting surfaces, the lower and the upper, are so effective that this form of the trap has proved more tenacious of its last inch or two of seal than a four-inch pot-trap, although its diameter is nowhere greater than that of the outlet and inlet pipes.

In this and in the preceding forms the depth of

seal is too great to allow of a free and rapid discharge of the wastes. The air, in passing through the trap, disturbs nearly all the water in it. Our next step will therefore be to diminish the height of the water-column through which the air has to pass, and thus reduce the disturbance of the water without lessening its volume. It may be done by laying the body of the trap horizontal instead of perpendicular, as shown in figure 13. This immediately

Fig. 13. Fourth step.

gives us a very important improvement in resisting power. The area of the trap is no greater than that in Fig. 11, but it is found to offer double the resistance to siphonage. Moreover, while the volume of water is the same as in Fig. 10, the seal is not so deep. Hence, the flow of water through this trap is more rapid than in the former, and its scouring effect correspondingly increased. As soon as the water in this trap has been lowered to the point indicated in the drawing, ample space is left above it for the passage of the air. It is evident that a much smaller body of water is disturbed by the passage of the air than is the case with the trap shown in Fig. 11.

Nevertheless, the trap thus made is not yet sufficiently antisiphonic. It is, moreover, awkward in form and difficult to set in such a manner that it shall remain firm in place. The long horizontal body is liable to sag and lose its form. Moreover, a single reflecting surface is insufficient to separate the water entirely from the air, and a strong and long-continued siphonic action destroys its seal. Other improvements are evidently necessary.

(To be concluded.)

## RUPTURE OF THE VAGINA DURING COITUS.<sup>1</sup>

BY JAMES R. CHADWICK, M.D.

RUPTURE of the vagina by the male organ is of so rare occurrence that its possibility has been denied by some writers of authority, hence I wish to put the following case on record.

Mrs. P. L., a woman of ordinary size and well developed in every way, applied at my dispensary on December 17, 1881, with the following story: She was forty-eight years of age, had begun to menstruate at the age of fifteen years, and had ceased at thirty-eight years. She had been six years married to a sailor, with whom she had cohabited freely without difficulty or pain. She had never been pregnant. On December 14th her husband had returned from four months' absence at sea, and had had connection. The act was accomplished

with difficulty. When it was effected she experienced a most intense lancinating pain on the right side internally. A profuse hemorrhage from the vagina ensued, which, however, ceased before morning. A purulent discharge set in on the second day, and on the third she consulted me. On examination I found that senile atrophy had taken place, as is usual after the menopause, so that the vagina was much shorter and smaller in calibre than is normal in the adult. On the right side was a fresh longitudinal rent, an inch in length, located in the upper third of the canal, and opening into the cellular tissue to the depth of half an inch.

If the woman's statements are truthful, as I believe, this laceration may be accepted as fully explaining the pain which she felt in coitus and the hemorrhage immediately succeeding. The accident must be attributed to the fact that the senile atrophy had advanced with exceptional rapidity in the period of four months' abstinence during the husband's voyage and to his undue vigor from the same cause.

Two cases of this lesion are reported by Dr. Zeiss, of Erfurt, in the *Centralblatt für Gynäkologie* for February 21, 1885. In the first case the rupture was merely an unusually deep tear of the hymen in a virgin on the first night of marriage, giving rise to a hemorrhage so profuse as to have endangered life. This occurrence is not unusual.

The second case was in a woman who had had a child three years before, and a second one six weeks previously. Coitus took place *à la ruche*, with exceptional vigor on the part of the husband, during which the woman experienced sudden extreme pain in the lower part of the abdomen on the right side; persistent hemorrhage ensued. The external genitals were found to be sound, with no signs of contusion. The uterus was greatly retroflexed. The dimensions of the vagina seemed normal. The cervix was firmly adherent to the right side of the pelvis. In the right vault of the vagina was seen a fresh rent an inch in length, into which the finger passed some distance.

## Reports of Societies.

### PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. M. GREEN, M.D., SECRETARY.

FEBRUARY 11, 1885. The President, Dr. A. D. SINCLAIR, in the chair.

Dr. W. L. RICHARDSON read the following communication on

#### CORROSIVE SUBLIMATE INJECTIONS.

In 1883 Negri<sup>1</sup> concluded an article on corrosive sublimate in puerperal antiseptics with the statement that a solution of one to 2,000 has sufficient antiseptic properties to combat puerperal septicæmia and can be substituted for a two per cent. solution of carbolic acid; that its toxic effects are almost nil, he having seen once only a case of mercurial erythema.

Although a solution of corrosive sublimate had been used for some time in Germany as an antiseptic

<sup>1</sup> Reported to the Obstetrical Society of Boston, February 11, 1885.

<sup>1</sup> Bulletin Général de Thérapeutique, October 30, 1883.

tic injection, I had never used it at the Boston Lying-in Hospital until my last term of service. When I came on duty in the spring of 1884 I continued its use, which had been begun in the winter by my colleague, Dr. W. E. Boardman. Very few cases, however, required an intra-uterine injection, and I therefore had few opportunities to observe its effects. For nearly eight months the hospital has been free from septic cases, but during December there have been three cases which occasioned some anxiety, one of them being a well-marked case of puerperal septicemia, and the other two presenting suspicious symptoms of septic poisoning, but in a much milder degree. These cases seemed to me to deserve mentioning as showing my experience with the use of corrosive sublimate as an antiseptic.

CASE I. M. A., Swede, multipara, twenty-three years of age, entered the Hospital November 9th. The child had been born on the train while coming from Gloucester. She entered the hospital at eight o'clock in the morning. The placenta came away in half an hour after her entrance. November 9th, the evening temperature being 100° F., and the lochia somewhat offensive, an intra-uterine injection (corrosive sublimate one to 2,500) was given and repeated the next day. November 12th, the intra-uterine injection was repeated, and, as the patient had had bilious vomiting during the day and no defecation since her entrance, calomel (five grains) and jalap (six grains) were ordered. November 14th, the gums were very tender and bled easily. There was a grayish deposit on the inside of the under lip and great pain on chewing. Astringent washes were ordered. The symptoms improved gradually, and she was discharged, December 1st, well. At the time I considered the salivation due to the calomel.

CASE II. C. M., twenty-two years of age, entered the Hospital December 1st: the child was born at six o'clock the following morning. Up to December 9th there were given, morning and night, vaginal douches of corrosive sublimate (one to 2,000), and, as the temperature was high and the lochia offensive, also three intra-uterines of the same. Upon December 8th the two left lower incisors were loose and the gum beneath them red and tender. Astringent washes were ordered. December 9th carbolic two per cent. was substituted for the corrosive, and the symptoms disappeared in two days.

CASE III. M. M., twenty-six years old, entered the Hospital December 2d at eight p.m. The child was born early the following morning. The patient received from the time of her entrance two vaginal injections daily of corrosive sublimate (one to 2,000), and, owing to the high temperature and offensive lochia, two intra-uterines of the same. December 5th. Complained of soreness of gums. December 6th. Complained of soreness of tongue. No especial attention was called to it until December 11th, when the upper and lower gums were reddened, especially near the teeth, and tender. No tenderness on closing the teeth sharply together. The lower lip was reddened on the inside, and there were to be seen small patches of gray exudation. The odor of the breath was characteristic. The tongue was very sore and red on the left edge and beneath, where there were also several patches of

thick gray membrane. The patient several times noticed an excess of saliva. On the morning of December 9th a change was made to carbolic acid (two per cent.) for douches and intra-uterines. The symptoms began at once to improve, and she was discharged, well.

Two other cases in which vaginal injections of corrosive sublimate (one to 2,200) had been given twice daily, presenting marked symptoms of incipient salivation. I substituted carbolic acid for corrosive sublimate during the remainder of my term of service, and shall never again return to the mercurial injection unless I change my present opinion of its danger.

Since writing the above I have heard of several similar cases occurring in private practice, and a physician in charge of the maternity wards of a large hospital has informed me of seven cases of salivation occurring in that hospital from the use of these injections: the strength of the injections in these cases was one to 2,500. Since that experience the strength of the injection was changed to one to 12,000, and no further trouble has been observed, although the injection has seemed to be sufficiently antiseptic in its character.

DR. INGALLS said that if, for instance, one grain of corrosive sublimate should be dissolved in two thousand drachms of water, and one quart of this administered by injection, the rather large proportion of the mercury, namely, one eighth of a grain, would cover the surface and be likely to produce mischief; if, however, one drachm of the one to 2,000 solution should be added to a quart of water one might feel sure of its being strong enough for his purpose and be unlikely to cause salivation.

DR. BAKER said that during the past year the one in 2,000 solution had been used at the Free Hospital for Women, both for irrigating denuded surfaces during operations and for washing out the uterine cavity: he had observed no bad results.

DR. DAVENPORT said he had used the intra-uterine sublimate injection in only one case, that of a sloughing fibroid: there was no salivation; but the patient complained of soreness and irritation about the vulva, and carbolic acid was therefore substituted for the bichloride. He was surprised that vaginal irrigation with the sublimate solution should be followed by salivation, as in two cases reported by Dr. Richardson, as the vagina does not readily absorb unless it is the seat of marked abrasions or lacerations: he had read, however, of diarrhoea following the sublimate douche in puerperal cases.

DR. RICHARDSON said, in reply to questions, that he had no knowledge that a one in 2,000 solution of the bichloride would destroy germs; in using the drug in that degree of dilution, he had relied upon the authority of others: from his clinical experience, however, he could say that a one in 2,000 solution destroyed the bad odor of fetid lochia and that its use was followed by a fall in temperature, when the elevation of temperature was attributable to septic absorption.

DR. O. W. DOE reported a case of

#### POLYGALACTIA.

DR. RICHARDSON said he had seen three or four cases of polygalactia in hospital practice, and had

had one case in private practice which very much resembled the one reported by Dr. Doe. The plan of treatment which he adopted consisted in weaning the baby, strapping the breasts, and administering fluid extract of ergot in half-drachm doses every three hours. He had been led to employ ergot in these cases from the observation of both Dr. Sinclair and himself in the Lying-in Hospital, that when ergot was given for several days after labor for the purpose of promoting the involution of the uterus or stopping afterpains the drug was very likely to arrest or retard the secretion of milk. In cases of hyper-secretion he had found marked relief to follow the use of ergot as he had stated.

Dr. CHADWICK favored strapping the breasts in these cases immediately after labor. He suggested that it might be advantageous to strap for several weeks before labor in the case of a patient who in previous labors had suffered with polygalactia.

Dr. DRAPER said that the use of ergot in these cases was based on a sound physiological principle, namely, the well known action of the drug on unstripped muscular fibre; strapping was simply a mechanical means of accomplishing the same result; certainly the combined use of the two agents was eminently rational.

Dr. REYNOLDS raised the question whether, if for any reason the mother is not to nurse her child, it is better that she should not nurse at all, or whether for the sake of the supposed effect of lactation on the involution of the uterus she should nurse for a few weeks. For his own part he doubted whether it was justifiable for such a purpose to subject a feeble patient to the strain of lactation.

Dr. BAKER said that so far as his observation went lactation unquestionably promoted the involution of the uterus: he therefore believed that the mother should be encouraged to nurse during the period of involution.

Dr. RICHARDSON remarked that a woman was far more likely to preserve the original contour of the breast if she nursed for a week or two: the breast usually became lax and flabby when the woman did not nurse at all.

#### THE TREATMENT OF THREATENED MASTITIS.

Dr. DOR said he had had good results from the use of belladonna ointment in ordinary cases of indurated breasts.

Dr. RICHARDSON said his treatment of such cases consisted in the free use of saline laxatives, proper support of the breast, and innunction with camphorated oil. He had formerly used belladonna ointment with good results; but he had equally good results with camphorated oil, and since he had instituted, at the Lying-in Hospital, the practice of carefully rubbing the breasts with this agent he had seen only five or six cases of broken breast, and these occurred in phthisical patients. He did not believe there was virtue in belladonna ointment other than that of any emollient.

Dr. SINCLAIR said he relied almost wholly on taking away the child and strapping the breasts: he believed the late Professor Buckingham had first advocated this treatment.

Dr. REYNOLDS remarked that Hardy and McClintock taught that the breasts should not be used; but

with threatening mastitis one does not want to give up nursing. Professor Buckingham believed that nursing on a cracked nipple was a common cause of mastitis: he thought the danger might often be averted by the use of a suitable nipple-shield.

Dr. GREEN said he had seen great benefit result from covering indurated breasts with thin sheet rubber, such as dentists use for a dam in filling teeth. The rubber retains the heat and moisture and therefore acts as a light poultice. From the combined effect of rubbing with camphorated oil and covering with the sheet rubber he had seen indurated breasts soften and their tension diminish by the spontaneous flow of the milk: in such cases he did not advise giving up nursing unless the nipple was badly cracked.

Dr. S. L. ARNOT reported a case of

#### UTERINE CARCINOMA OF UNUSUALLY RAPID DEVELOPMENT.

The patient was a married lady upward of forty years old, the mother of five living children, resident of a Western city. In the spring of 1881 she returned home after a visit to her native State, Rhode Island, much worn and reduced in flesh from attending her mother during her last illness. Having recruited somewhat, about the middle of May she thought she had a miscarriage at an early period. She also had an early miscarriage while on a journey during the autumn of 1883. Two weeks after the occurrence, in May, she had a chill, which was followed by discomfort in the uterine region. Her physician found, on examination, the uterus low down in the pelvis, pressing on the rectum, the cervix being somewhat shortened and bent forward. The whole organ was very hard, and increased from fifty to seventy-five per cent. above its natural size. The posterior surface was somewhat uneven. The organ was movable in all directions, but not freely, as if held by adhesions, although no inflammatory deposit about it could be detected. There was no swelling above the pubes. The uterus was somewhat tender, and the speculum showed moderate cervicitis. The condition of the organ was regarded as due to uterine engorgement, and considerable relief was obtained from rest, with hot douches and counter-irritation above the pubes. During July the patient was well enough to visit a Western health resort, where she lost ground, however, and became very feeble, with considerable emaciation, accompanied by gastric symptoms and colicky pains in the pelvic region. In this condition she left home on August 20th for a visit to Mt. Desert, in the hope of improvement from the sea-air. The catamenia had been regular up to that time, and came on soon after she reached Mt. Desert, being somewhat profuse and prolonged in period. During the rest of her stay she rode daily in an open wagon from three to five hours. She was treated during that time for her gastric symptoms, — gastralgia, vomiting, with diarrhoea, which were ascribed to hepatic disturbance, — with considerable relief. By the patient's desire there was no uterine treatment. She arrived in Boston in the last week of September, having come through by rail, a journey of fifteen hours, in one day. She was very much exhausted, was extremely emaciated, and in walking was much

bent over on account of the uterine discomfort when upright. For weeks she had not had a good night's rest, having taken no anodyne, and having at Mt. Desert suffered extremely from uterine pain at night. Suppositories of a small quantity of morphia in the rectum at once gave her great relief.

On vaginal examination the uterus was found very low in the pelvis, the os being just within the vulva, the neck being very much shortened and flattened, so much so as to project very little above the uterine mass, from an inch to an inch and a half wide; the os was patulous. There was no hæmorrhage or other discharge from it. The body of the uterus was so large as to be completely impacted in the pelvis, the surface in front and on the sides being perfectly smooth. From the posterior wall there was a projection backward from half an inch to an inch in height, an inch or more wide, which extended upward as far as the finger could reach, and very tender to the touch. The whole of the body of the uterus was of a stony hardness, but not specially tender except on the posterior surface. The posterior cul-de-sac was not more than two inches above the vulva. The abdomen was perfectly flat, and nothing abnormal could be detected in the abdominal viscera or by deep pressure above the pubes. The functions of the bladder were not disturbed, but the rectum was very sensitive to the pressure of feces, apparently from the pressure on the enlarged womb.

The patient's appetite was poor and taste capricious. Evacuations from the bowels were frequent, of small scybalous masses. By rest, soothing and anodyne remedies much relief from the local discomfort was obtained, the appetite improved, and the evacuations became nearly normal.

Ten days after the arrival of the patient in Boston the catamenia were due, and were anxiously expected in the hope of still further relief. As the case had been described in the letters which Dr. Abbot had received as one of congestion of the womb he was not prepared for the deplorable condition of things which he found, and after a few examinations he could not resist the conviction that he was dealing with a much more serious malady, in fact uterine carcinoma.

At the expected time there was a menstrual molen, as shown by a sense of fullness and pressure in the uterine region, but there was no catamenial flow. There was great increase of local discomfort and general disturbance of the system. In a day or two great tympanites appeared, the abdomen being distended to the utmost, and resonant throughout. During the rest of her stay in Boston this condition continued with very little relief, causing very great discomfort but very little pain. The patient left for her home October 8th, arriving, after a continuous journey of two nights and a day in the cars, in a better condition than could have been expected. Her medical attendant was at once struck by the great change in her appearance and condition, since he had last seen her in the latter part of August, and on consultation with a distinguished specialist was entirely satisfied that the case was one of carcinoma, not remediable by any surgical operation. At this time the abdominal distention continued, with marked evidence of the presence of fluid.

From this time the patient gradually lost ground, the appetite failed, and there was much nausea and vomiting, but little pain. She died quietly, November 13th. There had been no hæmorrhage or discharge of any kind after the catamenia ceased.

An autopsy was made seventeen hours after death. The abdominal cavity contained ten quarts of foul serum. Of the omentum majus only small fragments remained, attached to the stomach and transverse colon. The intestines were of a deep purplish copper color, the external surface being studded throughout with nodules of cancer. The pyloric orifice of the stomach, the head of the pancreas and duodenum were united in a cancerous mass. The inner surface of the pyloric orifice was much thickened and corrugated, and only a small portion of the mucous membrane of the stomach presented a normal appearance. Nothing abnormal was observed in the liver, spleen, or kidneys. The pelvis was filled with a mass of cancerous disease, the uterus and its appendages being firmly united to each other. The leading features of this case may be summarized as follows:—

Supposed miscarriage in the middle of May, followed in two weeks by a chill. At this time some enlargement of the posterior wall of the uterus and unusual hardness of the whole organ were detected. Gradual failure, with marked gastric symptoms and uterine pain. Catamenia regular, their last appearance being early in September. In the last week of September uterus found to be impacted in the pelvis from carcinoma developed in its walls, without any evidence that could be detected of similar disease in the abdominal cavity. Rapid development of abdominal symptoms from the time of catamenial failure early in October, with peritonitis and extensive deposit of cancerous disease in the abdominal organs.

Dr. J. R. CHADWICK reported a case of

RUPTURE OF THE VAGINA DURING COITUS.<sup>2</sup>

## THE NEW YORK ACADEMY OF MEDICINE.

STATED meeting April 16, 1885.

PRESENTATION OF A PORTRAIT OF THE FORMER PRESIDENT, DR. FORDYCE BARKER.

A handsome three-quarter length portrait of Dr. Barker, by J. H. Lazarus, was presented to the academy by Dr. T. M. Markoe, on behalf of the donors, Mr. and Mrs. John Jacob Astor, and accepted for the academy by the President, Dr. Jacobi. The academy is also indebted to Mr. and Mrs. Astor for the "loving cup" which graces its board on festive occasions.

Dr. JAMES B. HUNTER read a paper on

ENDOMETRITIS FUNGOSA: ITS PATHOLOGY, DIAGNOSIS, AND TREATMENT.

Having taken a glance at the literature of the subject from the writings of Robert and his master, Récamier, in 1816 and 1850, down to the paper on the use of the curette read by Dr. George T. Harrison, before the New York State Medical Associ-

ation in November last, he stated that he had never found fungous growths in the cervical canal, though they are not infrequently met with immediately beyond this. They resembled small polypi, and, while seldom exceeding five millimetres in diameter, are usually much smaller than this. Neither the number of the growths nor their size seemed to have any ratio to the amount of hæmorrhage resulting from their presence. They were of a pale pink color, had an abundant vascular supply, and there was always a distinct fibrous element in their structure.

They constituted a truly inflammatory tissue, and are characterized by no process at all akin to degeneration. It had often excited remark that such profuse hæmorrhage should result from such an apparently slight cause; but this was in reality not to be wondered at when the great extent of surface presented by the cavity of the uterus when studded with these growths was taken into consideration. The superficial area of the endometrium was enormously increased by the presence of even a few of them. In making a diagnosis of endometritis fungosa it was sometimes quite difficult to exclude sarcoma and epithelioma from the examination of a single specimen, and hence it was very desirable that repeated examinations should be made. Great care and perseverance were often necessary, therefore, in order to arrive positively at a correct diagnosis.

As to the symptomatology, the principal and, indeed, only symptom of importance was menorrhagia, pain being, as a rule, quite rare. In this condition the menstrual period was likely to be increased, while in carcinoma there was metrorrhagia, rather than menorrhagia. Sarcoma usually did not appear until after the thirty-fifth year; but endometritis fungosa might occur at any time during the child-bearing period as well as (though now rarely) both before and after the latter. The affection had no connection whatever with syphilis or gonorrhœa, but was often associated with uterine fibroids. Dr. Hunter then called attention to the differential diagnosis on the one hand between this and secret benign growths as polypi, adenomata, retained residua, papillomata (which are believed to be always confined to the cervical canal, and thus occupying a distinctly different position), and the so-called villous degeneration of the endometrium referred to by Goodell, and, on the other, from malignant affections. Among the latter, rounded sarcoma was most liable to be mistaken for it, and sarcoma was not so uncommon as Dr. Mundé, in his paper sent to the Edinburgh Obstetrical Society, in 1878, and other authors had stated. In addition to microscopic differences, there were certain points by which a differential diagnosis might be made, and among these were the following: In endometritis fungosa there was little pain, while in sarcoma the pain was apt to be a prominent feature. In the one there was, as a rule, menorrhagia; in the other, metrorrhagia. In the one the discharge was odorless; in the other it was offensive. In the one the growths were of a pale pinkish color and firm in consistence; in the other they were grayish-white, amorphous, and very pliable. In the one there was no infiltration of the surrounding tissue; in the other there was marked infiltra-

tion, and the surrounding mucous membrane was destroyed. In the one the pathological changes were confined to the mucous membrane; in the other they involved the body of the uterus also.

The treatment of the fungous growths themselves was very simple, consisting merely of their removal from the endometrium by means of the curette. The treatment of the condition which gave rise to them, however, was generally a more difficult matter, and on the success of this would depend the prospect of a return of the fungosities. In his own experience he had never found it necessary to produce dilatation of the cervical canal before using the curette, as the mouth of the uterus was always sufficiently patulous for the purpose. He thought it was better to etherize the patient, as the growths could be more thoroughly and satisfactorily removed when this was done. Sims's speculum was placed in the vagina, and the instrument was the Thomas blunt copper-wire curette. After the curetting, Churchill's tincture of iodine was thoroughly applied to the whole endometrium, and, a light tampon having been inserted, the patient was put to bed for two days.

The use of the curette had an excellent effect in reducing the congestion of the mucous membrane of the cavity of the uterus, even when no fungosities are present. The contra-indications for resorting to the curette were recent pelvic inflammation or the existence of any degree of parametritis. Récamier's original curette was, undoubtedly, a cutting instrument. It had recently been claimed in England that it was blunt; but there was, in reality, no evidence that such was the case. Both Sims's and Simon's curettes were also cutting steel instruments. In the curette of Dr. Thomas, which he devised about 1870, the bluntness was the important factor, and it was the first one of its kind. Two sizes of the instrument were used. Emmet's curette-foreceps was an entirely different instrument. The blunt curette was perfectly safe, and, as it was thoroughly efficacious in removing fungous growths, he thought that it was greatly to be preferred in this class of cases.

Dr. W. GILL WYLLIE said that he objected to Dr. Hunter's treatment in some respects. He agreed with him in the statement that the use of the curette was seldom followed by hæmorrhage, and he was, therefore, somewhat surprised to hear him say that he was in the habit of employing a light tampon after curetting. For himself, he never used a tampon if he could possibly avoid it, because he considered it a violation of one of the first laws of surgery—thorough drainage. Even in cases of cancer he preferred to stop hæmorrhage in some other way. By twisting the circular artery, if it had been injured, and by the application of hot and cold water styptics or pure carbolic acid, waiting an hour if necessary for the bleeding to cease, he would endeavor to avoid the use of the tampon. Before antiseptics were employed it was well known how oppressive the tampon would get, and although this might be obviated to a great extent by the use of bichloride of mercury and iodoform, he believed there was always a liability of irritating fluid being forced up into the Fallopian tubes. He was in the habit of practising dilatation in all cases, and prin-

cipally for the purpose of securing more perfect drainage. In addition, even though the os was quite patulous, there was always danger of injuring the cervical tissues with the curette unless further dilatation were made. He was, of course, thoroughly opposed to the use of sponge tents on account of the danger of septic absorption, and invariably used Sims's steel dilators. He also employed Sims's steel curette, and in regard to this instrument he thought great injustice had been done Dr. Sims. The so-called sharp Sims's curette was not, in reality, a sharp curette, although it was true that it was made of steel. At first it had been made with a flexible shank, but afterward it had been found that it was advisable to have it constructed with one universal curve. If a tenaculum were employed in connection with the curette any uterus could be straightened to such an extent as to admit of having the instrument satisfactorily applied to every portion of its cavity. The advantage of the steel curette over the dull copper one was that it did the work desired more thoroughly, while, at the same time, it did not injure the normal tissue. In many cases he believed that the blunt curette was not sufficient, because it could not remove the fungosities perfectly. Sarcoma could also be removed very thoroughly with the steel instrument.

Dr. P. F. Muxé stated that since he had sent his paper to the Edinburgh Obstetrical Society, to which Dr. Hunter had referred, some years ago, cases of sarcoma had accumulated; the disease having of late become much better known than formerly. He thought Dr. Hunter ought to have devoted some attention to the agency of laceration of the cervix in inducing endometritis, as he believed that it was often a very important etiological factor. Having dwelt for some time on this point, he spoke of the occurrence of amenorrhea in certain cases of fungous growths; the patient sometimes going for five or six months without any appearance of the menses, and then having quite a profuse flow. In his Edinburgh paper he said he had advocated the use of the blunt curette; but since that time he had modified his views in regard to this instrument to some extent. While he was still an advocate of its use in many cases, he now agreed with Dr. Wylic that there are also many cases where the blunt curette was not sufficient; the sharp instrument being required in order to eradicate the growths. In such cases it was necessary to scrape down the mucous membrane almost to the substratum. Still, he did not think it was advisable to use a stiff curette or one with which we could scrape through the uterine wall. A fairly flexible shank was preferable. The dull curette was very useful for diagnostic purposes, and if in any instance no fungosities were brought away with this, he concluded that the case was not suitable for curetting. In regard to the after treatment he disagreed with Dr. Wylic and accepted the position of Dr. Hunter. When there was subinvolution there was very apt to be pretty free hemorrhage, and he was often glad to plug both the uterus and the vagina. He did not believe it was a good plan to curette a patient except at her own house and under the influence of an anæsthetic, and he did not think it was safe to leave the house without having placed a tampon in

position. After using the curette he made an application of either tincture of iodine or of a mixture of equal parts of solution of persulphate of iron and glycerin; after which he placed a tampon in the vagina. He regarded this procedure in the light of an operation, and always called within forty-eight hours to remove the tampon. Applications of iodine to the endometrium, he thought, ought to be made twice a week at first, and later once a week; and he regarded it as very important that the after treatment should be maintained for a sufficient length of time.

Dr. C. C. LEE said he concurred, in the main, in the views expressed by Dr. Hunter. In regard to the symptomatology, however, he thought that the condition was not necessarily characterized by menorrhagia. Metrorrhagia, he believed, was a well-marked symptom in quite a large minority of typical cases, general passive uterine congestion being usually present. In treating endometritis fungosa he always prepared the case carefully before operating, and when using the curette preferred to give ether. In the choice of instruments he had no hesitation in declaring himself strongly in favor of the blunt curette, as he believed the sharp curette was quite as likely to do injury as good, even when employed by the most skilful hand. One of the worst cases of pelvic peritonitis which he had ever seen had been directly caused by the application of a sharp curette by a gynecologist of high reputation. He did not find it necessary to practise dilatation, as the cervical canal was always sufficiently patulous in these cases. He made it a rule always to wash out the cavity of the uterus, both before and immediately after using the curette, with a weak solution of carbolic acid. In addition, after curetting, he applied a solution of strong tincture of iodine to which was added a small quantity of chromic acid, a combination which he had found to have a more permanent effect on the uterine mucous membrane than any other.

Dr. B. F. Dawson said he was heartily in accord with Dr. Hunter. The mildness of the blunt curette constituted its great advantage. Dr. Mundé had said that if he were unable to extract any granulations from the cavity of the uterus with the blunt curette he did not use the sharp instrument, and if such was the case he could not see why he should ever use the sharp instrument at all. Only recently he had seen a very aggravated case of pelvic cellulitis which followed the application of the sharp curette. He did not think it was necessary to practise dilatation, since uterine catarrh was a constant accompaniment of the condition of fungous granulations, and whenever there was uterine catarrh there was sure to be a patulous os.

Dr. HUNTER said that he was in the habit of using a light tampon for antiseptic purposes, and that he had not found it necessary to employ it for the controlling of severe hemorrhage, like Dr. Mundé. When there was very great hemorrhage following the use of the curette he was inclined to think it was due to the fact that all of the growths had not been removed. The dilatation of the cervix, as recommended by Dr. Wylic, he thought was much more likely to do injury to it than the careful use of the curette. He had mentioned laceration of the cervix

as one of the causes of endometritis fungosa, but as it was not his intention to make the paper an exhaustive one he had not had time to dwell upon it at length. Like Drs. Lee and Dawson, he also had seen instances, one of which was now under his care, in which very serious consequences had resulted from the use of the sharp curette.

### THE AMERICAN SURGICAL ASSOCIATION.

THE American Surgical Association held its annual session in the Army Medical Museum at Washington, April 21, 22, 23, and 24, 1885.

The President, WILLIAM T. BRIGGS, M.D., of Nashville, Tennessee, in the chair.

The morning session of Tuesday was called to order at eleven A.M.

The first business was the reading of the President's address. In the beginning of his address the President thanked the association for the great honor conferred upon him by his election. He then spoke of the great loss which their organization had experienced in the death of Prof. S. D. Gross, referring eloquently to the labors of Dr. Gross in organizing and establishing the American Surgical Association in its present position.

In order that the association might deserve its name as the national society and its claim to a representative body, the speaker thought it essential that every reputable surgeon should be eligible to membership. And, if necessary, the constitution should be so altered as to provide for a greater membership than it now does. It was only in this way that the strength and vigor of their society could be maintained. Every member should consider it his duty to be present at all the annual meetings, and to be prepared to take part in the debate.

He also suggested that the original intention of the society be adhered to, and the meetings held in the fall of the year or latter part of the summer, at the time when most of the members need rest, so that they could combine with the work of the association, rest and recreation. It was also suggested that it might be advisable to hold the meeting at some summer resort.

He recommended that the council select the names of some foreign surgeons to be presented for election to the position of honorary members.

The suggestions of the President were referred to the consideration of the council.

The first paper of the session was entitled

#### A DEVICE FOR ATMOSPHERIC PURIFICATION.

By DAVID PRINCE, of Jacksonville, Illinois.

The following is a description of the device:—

(1) **BASEMENT.**—On the right hand is an entrance ventilator, twenty inches in diameter, in which a steam-jet is made to play, in order to infiltrate the entering air with very fine globules of water.

(2) The air thus moistened passes under a curtain or diaphragm reaching within fifteen inches of the floor. Under this curtain lies an iron pipe, with numerous small holes drilled in the upper side, furnishing an interrupted spray under the curtain, and making it necessary for all the moving air to pass

through this artificial shower near to the floor and into the next room warmed by a stove.

(3) The air, thus warmed, passes through a filter, composed of shelves of thin muslin through which water is dripping. The warmed air first passes over the top of a vertical screen to avoid the entrance of cold air, then under another vertical screen, and then back and forth between horizontal screens fifteen inches apart, dripping with water, and finally through the spray which supplies this water.

Thus there are three filtrations of the air: one by steam and two by water.

(4) The air thus filtered three times emerges through an opening in the floor and goes to the top of the operating-room above.

(5) **OPERATING-ROOM.**—The exit ventilation is seen on the opposite, or right hand, side of the room. This is effected by a movable shaft or box, made by tacking muslin upon a frame, so that it can be set up against a window, with the upper sash pulled down to the necessary degree. The shaft can be shifted from one window to another to be free from the pressure of the wind, or on the opposite side, or from the wind. The arrangement, thus far, is to get an atmosphere more pure than that outside, and through the frequent change of the air in the operating-room, to get rid, to the greatest possible degree, of the contamination of the air (during the progress of an operation) by the emanations from surgeons, assistants, spectators, and the patient himself. This change is secured by the entrance of filtered air from the basement and the exit, from the floor of the operating-room, of the air which has been the longest in the room, having descended gradually from the ceiling where the air is hottest, after having entered from the warming-chamber below.

(6) The floor of the operating-room is made of yellow pine, and filled with paraffin to as great a depth as heated smoothing-irons can drive it. By this means, all cracks are filled so as to be non-absorbing. Under this lies a layer of tarred paper upon a common floor upon the joists. Between the joists lies a layer of tarred paper upon the ceiling, the under side of which ceiling is painted, and lined with muslin while the paint is fresh. The muslin is again painted on the under side. The floor thus has seven layers, including the joists.

(7) The operating-room is free from closets where anything unclean can be hidden, and all woodwork is either paraffined or painted.

(8) There is no opening into any other room, about six feet of space intervening between the door of entrance and the nearest wall of the main building.

(9) Before the use of the room for an operation involving the opening of a joint or the peritoneal cavity, it is intended that the rooms above and below shall be fumigated by sulphur burning in the basement. An iron pan for this purpose is placed over a Bunsen burner for the combustion of sulphur. This is to be done for the destruction of any floating material of an organic character which may have gained entrance while the room may have been out of use.

It is found by trial that when the different sprays

of water are going, one can remain very comfortably in the room above while sulphur is burning in the room below; the fumes being first absorbed by the steam and having then to pass through the two different showers of water become thoroughly precipitated.

(10) This building is the execution of a theory of combining the best known expedients for securing the best possible atmosphere for surgical operations, by excluding noxious agents and by destroying or expelling those which may have stolen in, or which may be introduced by the patients, or by the surgeon and his assistants and guests. It is supposed that enough air will enter and escape to change the whole volume of the air once in fifteen minutes. The exit draft coming from the floor will carry away most of the floating material.

(11) The employment of a spray or douche of carbolic acid of the strength of 4 to 100, or of mercuric bichloride of 1 to 10,000, or other antiseptics, locally applied, though less necessary than in an ordinary room, may yet be resorted to in order not to omit any useful precaution.

(12) The employment of solutions of carbolic acid, mercuric bichloride, or permanganate of potash with the nailbrush for cleaning the hands, should be supplemental to the fixed provisions against septic and pathogenic particulate infection.

(13) The lathing of the instruments in carbolized water, while this proceeding is incapable of disinfecting or destroying any germs which may adhere to them, may yet be useful in an antiseptic sense, that is, by destroying microbes in a developed state or freeing them from the supposed secretion by which they may be surrounded, and which may serve as their weapon of attack by which they digest or destroy the surfaces with which they come directly in contact.

(14) A useful precaution on the part of the operator may be a bath and a change of clothing, the hair and head being dampened so that dust will not escape from them; and yet another precaution may be the wearing of gowns, which will oblige all dust escaping from the clothing of the operator and his assistants to fall to the floor, whence it may escape with the draft which carries out the lowest stratum of the air.

Adjourned.

#### AFTERNOON SESSION.

#### THE FIELD AND LIMITATION OF THE OPERATIVE SURGERY OF THE HUMAN BRAIN.

By JOHN B. ROBERTS, M.D., of Philadelphia.

The following views were advanced:—

(1) The complexus of symptoms called "compression of the brain" is not due so much to displacing pressure exerted on the brain substance as it is to some form or degree of intracranial inflammation.

(2) The conversion of a closed (simple) fracture of the cranium into an open (compound) fracture by incision of the scalp is, with the improved methods of treating wounds, attended with very little increased risk to life.

(3) The removal of portions of the cranium by the trephine or other cutting instruments is, if properly done, attended with but little more risk to

life than amputation of a finger through the metacarpal bone.

(4) In the majority of cranial fractures the inner table is more extensively shattered and splintered than the outer table.

(5) Perforation of the cranium is to be adopted as an exploratory measure almost as often as it is demanded for therapeutic reasons.

(6) Drainage is more essential in wounds of the brain than in wounds of other structures.

(7) Many regions of the cerebral hemispheres of man may be incised and excised with comparative impunity.

(8) Accidental or operative injuries to the cerebral membranes, meningeal arteries, or venous sinuses should be treated as are similar lesions of similar structures in other localities.

(9) The results of the study of cerebral localization are more necessary to the conscientious surgeon than to the neurologist.

An elaborate table of the proper points for trephining in various cerebral lesions was then given.

These principles of the operative surgery of the brain were then applied to the treatment of (A) Cranial Fractures.

*Closed (simple) Fissured Fractures.* (1) No evident depression, no brain symptoms. No operation.

(2) No evident depression, with brain symptoms. Incise scalp and trephine.

(3) With evident depression, no brain symptoms. Incise scalp and possibly trephine.<sup>1</sup>

(4) With evident depression, with brain symptoms. Incise scalp and trephine.

*Closed (simple) Comminuted Fractures.* (5) No evident depression, no brain symptoms. Incise scalp and probably trephine.<sup>2</sup>

(6) No evident depression, with brain symptoms. Incise scalp and trephine.

(7) With evident depression, no brain symptoms. Incise scalp and trephine.

(8) With evident depression, with brain symptoms. Incise scalp and trephine.

*Open (compound) Fissured Fractures.* (9) No evident depression, no brain symptoms. No operation, but treat wound.

(10) No evident depression, with brain symptoms. Trephine.

(11) With evident depression, no brain symptoms. Possibly trephine.<sup>1</sup>

(12) With evident depression, with brain symptoms. Trephine.

*Open (compound) Comminuted Fractures.* (13) No evident depression, no brain symptoms. Probably trephine.<sup>2</sup>

(14) No evident depression, with brain symptoms. Trephine.

(15) With evident depression, no brain symptoms. Trephine.

(16) With evident depression, with brain symptoms. Trephine.

*Punctured and Gunshot Wounds.* (17) In all cases and under all circumstances. Trephine.

<sup>1</sup> In classes 3 and 11 he would be inclined to trephine if the depression were marked, or the fissures sufficiently multiple to approach the character of a comminuted fracture.

<sup>2</sup> In classes 5 and 13 he would trephine, unless the comminution were found to be inconsiderable.

(B) Intracranial hæmorrhage. Trephine for the removal of clot and arrest of bleeding when the probable seat of hæmorrhage is ascertainable, and the clot is believed to be a localized one.

(C) Intracranial suppuration. Trephine, and make, if necessary, exploratory punctures in all cases of abscess.

(D) Epilepsy following cranial injury. Remove portion of cranium in selected cases.

(E) Insanity following cranial injury. Remove portion of cranium in selected cases.

(F) Cerebral tumor. If can localize it, and if it is probably superficial, remove bone; and excise growth if it is found.

#### DISCUSSION.

DR. HUNTER MCGUIRE, of Richmond, thought that the doctrines advanced were dangerous ones to promulgate. There were only two conditions in the whole list in which we were told not to trephine. In all other cases trephining was either positively recommended or its necessity considered possible. The adoption of these principles would carry surgery back many years. The first proposition he could not consider as entirely correct, since in some cases where the symptom of compression follows immediately the occurrence of the accident, there was not time for the occurrence of inflammation. He thought that it would not be wise to convert a simple fracture into a compound unless there was some necessity for it, for this did undoubtedly increase the risks. He agreed with the author in reference to the importance of drainage, and in order that this might be perfect, he had in his last case removed a portion of the scalp.

He then described a case of epilepsy of two or three years' standing from punctured fracture in which he applied the trephine. In this case there was a sudden gush of the cerebro-spinal fluid when the button of bone was removed. The patient recovered without trouble.

In a second case in Richmond lunatic asylum, that of a colored man who had received a punctured fracture nine years previously, and who had not uttered a word since the injury, he trephined and in a few hours the patient was talking rationally, and has since recovered entirely.

DR. MOSES GINN, of Chicago, agreed with most of the opinions expressed by Dr. Roberts. He had himself three years ago enunciated similar doctrines. He held that depressed fractures of the cranium, whether simple or compound, were to be treated by elevation of the depression. The mere act of removing a portion of the cranial walls is not a dangerous procedure. The rules which have been given to-day, if used with judgment, will be of the greatest benefit to the human race. He said he must agree with Dr. McGuire when he says that in some cases the symptoms of compression are due directly to the depressed bone, but he believed that many of the instances spoken of as simple compression are due to irritation and inflammation.

DR. CHARLES B. NANCREDI, of Philadelphia, agreed with the previous speakers in regard to the first proposition. The nature of the process in these rare cases is unknown. It may be due to a spasmodic contraction of the capillaries of a portion of

the encephalon from the irritation of a sensitive nerve. He could not agree with the second proposition, for the trephining was always associated with the liability to certain accidents which it was often impossible to avert, and he thought that the risks of trephining could not be compared to those of amputations of a metacarpal bone. He agreed in the fourth proposition, but did not consider it necessary to make the exploratory operation as suggested by Dr. Roberts. He acknowledged the importance of drainage. The seventh proposition he dissented from. The speaker described one case of hæmorrhage from the superior longitudinal sinus which had been controlled by a compress sprinkled with iodoform. He had carefully studied the subject of cerebral location, and thought that the motor points were pretty well determined, but considered that there would be great risk in basing an operation wholly on irritation of sensory centres, relating a case bearing on this point.

As regards treatment, there are some cases in which the concomitant injury to the brain is so great that whether trephining is performed or not the patient will die. These deaths are often erroneously attributed to the operation. A second class is at the other extreme. Here the lesions are so slight that if the secondary effects are prevented recovery will occur. In this class there is a medium between the two, and in these trephining is usually called for.

He did not consider the puffy tumor so significant of suppuration as did Roberts. He connected it with osteomyelitis, in which suppuration is often present. In cerebral abscess, he had found the temperature normal and subnormal.

DR. W. F. PECK, of Davenport, Iowa, believed that pressure of bone might directly cause the symptoms of compression, but that these were more commonly due to the secondary effects of the injury.

He related several cases. The first was that of a brakeman struck in the temporo-parietal region on the right side. There were immediate symptoms of compression, which continued for twenty-four hours. After trephining they gradually disappeared.

Four days later he had a convulsion, and examination showed the presence of pus in the brain, which was removed by incision, about an ounce of pus escaping.

The second case was that of a child shot in the frontal region. The skull was trephined, and a clot of blood escaped; drainage was practised, and the child recovered.

In a third case, a child, there was produced a fracture with depression of half an inch without any symptoms. Nothing was done, and the child is still well.

DR. T. F. FRETWELL, of St. Louis, considered the propositions advanced too sweeping, and thought that the paper should be thoroughly discussed. The symptoms of compression might be due to compression from bone or effused blood, and it is not rare to have the symptoms from the latter cause. The second proposition may be true, but still trephining should not be done without good reason. The results of a blow upon the head are not simply from the fractured bone, but are also dependent upon the effect on the brain and meninges. The fracture of the bone is not more im-

portant than fracture of any other bone. Although the antiseptic treatment gave us some control over the course of wounds, yet a compound fracture was still more serious than a simple one, and authorities are not agreed as to the value of antiseptics.

In children depressed fractures are frequently not followed by symptoms of compression. The trouble is most likely to be produced where the depressed bone proves a source of irritation to the brain and membranes. Where there is simple depression without symptoms I think that we can afford to wait.

In regard to hæmorrhage, if we believe the bleeding is going on, and the patient is going to die from the compression, it would be advisable to trephine. If symptoms were not urgent it would not be advisable to trephine. A certain amount of blood will be absorbed. If the blood is in the arachnoid space trephining would be of little service.

DR. CHAS. T. PARKES, of Chicago, did not think it proper to compare trephining with amputation through a metacarpal bone. He dissented from the fifth proposition.

He described a case showing the amount of injury which a brain might receive without production of positive symptoms. In this case there was fracture in two or three places, there being depression at vault. This was trephined. Three or four days later there was a flow of cerebro-spinal fluid from the drainage-tube. This he referred to a laceration of brain substance extending to the ventricle.

In a wound of the longitudinal sinus he controlled hæmorrhage by inserting stitches.

He described a case of fracture in which a large portion of the brain substance lying above the tentorium of the cerebellum was lost. There was, however, no evident alteration of sensation.

DR. J. COLLINS WARREN, of Boston, referred to the difficulty of securing thorough drainage on account of the bulging up of the brain tissues which occluded the opening. The brain is then apt to press upon the sharp edges of the opening and cause irritation. He then referred to the difficulties of diagnosis, relating several cases. A child had received a depressed fracture. At first there were no brain symptoms. There was some fever. In a week complete deafness manifested itself, and the child soon died. The autopsy showed pus in the fourth ventricle. In such a case trephining would have been of little service, although the aspirator might have been used.

In another case, the patient, a man, was unconscious and delirious for four weeks before he died. After death no lesion of the brain could be discovered, but a large amount of clotted blood was found in the peritoneal cavity. A case was also cited bearing on the localization of cerebral injuries from the symptoms.

DR. McLANE TIFFANY, of Baltimore, thought that a line must be drawn between the fractures in childhood and those in adult life. There is also a great difference in the effect of such injuries in the negro as compared with the white race. In the former they are not nearly so serious.

DR. S. W. GROSS, of Philadelphia, referred more particularly to gunshot injuries of the skull, and said that he considered drainage in wounds of the brain to be more essential than in wounds of other

parts. He spoke of the case of Noyes, in which a counter-opening was made and a drainage-tube carried through. He thought that the principles which guide the treatment of wounds of other soft parts should be applied to the brain, and referred to the case of Fluhrer, in the *New York Medical Journal*, in which the course of the bullet was determined, a trephine applied over the opposite side of the skull and the ball removed.

DR. E. M. MOORE, of Rochester, endorsed the views of Dr. Gross. He considered drainage of great importance. He described a case in which he had traced the course of the bullet with a probe, trephined and removed it, and recommended the passage of a drainage-tube through the brain.

The further discussion of this paper was postponed until Wednesday morning.

Adjourned.

#### WEDNESDAY MORNING.

The discussion of Dr. Roberts's paper was resumed.

DR. DAVID PRINCE said that use of antiseptics in these cases had made the practice of trephining much safer than it had formerly been. The doctor then related a case showing the difference in result in cases treated with and without antiseptic precautions.

DR. JOHN H. BRINTON thought that the first thing that a surgeon looked for in a case where there were symptoms of compression was depression of bone. He thought that such depression could cause the symptoms. He described a case in which there was a fracture from one external angular process to the one on the opposite side, with overlapping of the fragments. There were marked symptoms of compression, which were at once relieved by replacing the bone. He thought that the only cases in which there could be difficulty in determining the proper course to pursue were those cases where there was a simple depressed fracture with no, or very slight, symptoms. He considered the best treatment in such cases to be operation, in order to avoid the sequelæ of such injuries, and read from Gross's *Surgery* extracts advocating this plan of treatment.

DR. THEODORE MCGRAW, of Detroit, described a case to show that although in children the brain might accommodate itself to pressure yet such was not the case in adults. A negro fell striking his head and produced a fracture which was cup-shaped. He was at first stunned, but was soon able to return to work. Dizziness after a time showed itself and this increased until a year after the accident, when he was obliged to quit work. The depressed bone was then trephined and the internal plate was found to be perfectly smooth and the dura mater was free from all evidences of irritation. The man immediately recovered and is now able to work on the highest buildings.

DR. P. S. CONNOR thought it better to use the trephine than to expose the patient to the after effects of these accidents. In the case of gunshot wounds, he did not think the treatment spoken of entirely proper. The operation of trephining he thought was not a trivial one, but the conditions in the cranial bones were different from those found in other bones of the body.

DR. WATSON, of Jersey City, described a case in

which depression of the skull of an adult was recovered from without operation, although there were at the time of the accident marked symptoms of cerebral irritation, and even after recovery the man could not indulge as freely as formerly in the use of alcoholic liquors.

The President, Dr. BRIGGS, was then called on to give his views. He divided cranial injuries into two classes, one in which the force was diffused and the other in which it was localized. In the first class trephining was of no service. In the second class trephining is appropriate. It is only in those cases, in his opinion, where the bone is doing the damage that the trephine is to be employed.

In the majority of those cases where compression is said to be due to depression, I think the operation is unnecessary. Where blood is poured out producing compression, it is different, and the trephine may be used, although with little hope of saving the patient. Where there is formation of pus the trephine is to be used on the same principle as the lancet is used in the case of soft tissues, to evacuate the pus.

The principal and only use of the trephine, in his opinion, is to remove points of irritation, produced by spicules of bone.

The trephine is to be resorted to to prevent those changes which, if once established, cannot be removed. The operation will prevent and limit inflammation. The field of the trephine is preventive and that alone. In the actual operation of trephining there is no danger. If the operation is done carefully it cannot be dangerous. The danger comes from the associated conditions.

Dr. ROBERTS, in closing the discussion, said that he made a distinction between the terms compression and pressure. By compression he meant squeezing. This was not produced in ordinary cases of fracture. The brain was so soft and its communication with the spinal canal so free that it was impossible to produce pressure to any extent.

He attributed the symptoms in those cases in which the accident was immediately followed by signs of compression to shock, laceration of the brain, or concussion. Inflammation, he thought, could develop in the brain more rapidly than was generally supposed. He supported his statement that trephining entailed but little more risk than did amputation of a metacarpal bone by presenting the statistics of the two operations. In regard to exploratory operations in obscure cases, he thought that the little risk of the operation had better be taken than to run the risks of serious consequences from the neglect of the operation. A careful reading of his propositions would show that he did not recommend trephining in all cases of fracture save two, as had been stated.

#### NEPHRECTOMY: ITS INDICATIONS AND CONTRA-INDICATIONS.

By S. W. GROSS, M.D., of Philadelphia.

The operation, he thought, was performed too frequently, and the object of his paper was to point out the scope of the operation. After a careful study of the statistics of the operation he presented the following conclusions:—

I. That primary extirpation of the kidney is indicated, first, in sarcoma of adult subjects; secondly, in the early stage of tubercular disease; thirdly, in rupture of the kidney or of the ureter; and fourthly, in benign tumors.

II. That nephrectomy should not be resorted to until after the failure of other measures; first, in urinary fistula of the kidney or of the ureter; secondly, in protrusion of the kidney through a wound in the loin; thirdly, in recent wounds of the kidney or of the ureter made in the performance of ovariectomy, hysterectomy, or other operations; fourthly, in suppurative lesions; fifthly, in hydro-nephrosis and cysts; and, lastly, in floating kidney.

III. That the operation is absolutely contra-indicated, first, in calculus of an otherwise healthy kidney; secondly, in sarcoma of children; thirdly, in carcinoma at any age, unless the disease can be diagnosed and removed at an early stage; and, fourthly, in the advanced stage of tubercular disease.

#### NEPHROLITHOTOMY.

By L. McLANE TIFFANY, M.D., of Philadelphia.

This was the report of a case in which the doctor had performed this operation. The kidney was reached through the lumbar region. A needle was introduced and the stone felt. A digital examination was then made and it being determined that the calculus was too large to be removed in its entirety, it was broken with a spoon and removed by a stream of water. Its total weight was 556 grains. A drainage-tube was introduced and a dressing of iodoform and oakum applied. The patient recovered without any bad symptoms.

The doctor thought that the best plan of opening the kidney was to pass directly through the renal tissue without attempting to reach the pelvis or to work around to the back of the organ. There was then less danger of a fistula. The hemorrhage was readily controlled with hot water.

A full description of the symptoms calling for the operation and the details of the operation was then given.

Dr. J. W. S. GOWLEY said that a case of a similar operation was reported to the New York Medical Association.

Dr. McGRAW, of Detroit, stated that there were but few cases of stone in Michigan, but these cases were attributable to stricture in some portion of the genito-urinary apparatus.

The further discussion of the case was taken part in by Drs. Gross, Connor, Prewitt, and Tiffany.

The afternoon was occupied by a visit to Johns Hopkins University.

#### Recent Literature.

A *Textbook of Practical Medicine, Designed for the Use of Students and Practitioners of Medicine.* By ALFRED LOOMIS, M.D., LL.D., etc. etc. With two hundred and eleven illustrations. New York: William Wood & Co. 1884.

Dr. Loomis is well known as a visiting physician to Bellevue Medical College and Professor of Pathological Anatomy and Practical Medicine in the Medical Department of the University of the City

of New York. This thick octavo volume of 1,100 pages on Practical Medicine is practically, as he tells us, a revision and an elaboration of lectures given during the last eighteen years. The classification of disease adopted is that which he has followed as a teacher; he has selected for description those types of diseases commonly observed by the American physician, and has indicated the treatment usually followed in this country. He has endeavored to avoid the discussion of unsettled questions, referring to such in brief footnotes. The morbid changes and objective symptoms of disease are, as the title-page shows, extensively illustrated by plates.

There is a short introductory chapter on Inflammation, and the rest of the book is divided into six sections. Section I. treats of diseases of the respiratory organs; II. of diseases of the digestive system, including those of the liver, spleen, and pancreas; III. of diseases of the heart, bloodvessels, and kidneys; IV. of acute general diseases; V. chronic general diseases; VI. of diseases of the nervous system, including diseases of the brain, spinal cord, and functional nervous diseases.

In the matter of treatment Dr. Loomis impresses the reader as being moderate and conservative. We notice with some surprise that he condemns, and that quite strongly, the practice of washing out the chest in empyema with a permanent opening, even when the discharge is offensive. He is opposed, and we believe very rightly, to cold applications in pneumonia, and regards venesection, cardiac sedatives, and counter-irritation as productive of more harm than good. He is not in accord with the Germans as to the extreme danger of pyrexia, but thinks moderate doses of quinine and the seasonable use of cold baths, especially in typhoid fever, are in some pyretic conditions, and before the end of the second week in typhoid, of much service. His views and rules for the administration of stimulants are eminently sensible and practical.

To Professor Loomis's students past, present, and future this book should be very acceptable. Others will find it useful for reference. Its bulk detracts somewhat from its convenience as a handbook. The illustrations are for the most part sufficiently clear and satisfactory to add decidedly to the value of the text.

Notwithstanding what we have been glad to say in praise, and not losing sight of the purpose of this volume, we still suspect if the writer were a less busy man he could have produced a book which would have added more to his reputation than this is likely to do, and one which would have been a more lasting addition to American medical literature.

—A prize of 5,000 francs and a gold medal, offered by the Emperor of Germany for the best model of a soldiers' barrack and field hospital, is to be awarded at the forthcoming Antwerp exhibition, and American inventors are invited to compete. The barrack must be large enough to contain twelve beds. It must be easy of transportation, made with interchangeable parts, and capable of being taken down and reconstructed.

## Medical and Surgical Journal.

THURSDAY, APRIL 30, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by CUPPLES, UPHAM & Co., Boston. Price, 16 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canadas. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM AND COMPANY,

283 WASHINGTON STREET, BOSTON, MASS.

### THE EARLY DAYS OF THE CONNECTICUT MEDICAL SOCIETY.

The Medical Society of the State of Connecticut has felt the propriety of rescuing its early records from the destruction which so rapidly consumes unvalued manuscripts and has published a volume which contains the early transactions and certain literary papers which illustrate medical knowledge and modes of action in the latter days of the last century.

An attempt was made to establish a State Medical Society in 1763, which was unsuccessful; but the memorial of the physicians of Norwich is considered sufficiently curious to repay reproduction. It commences:—

“The Memorial of us the Subscribers Physicians in Said Colony Humbly sheweth That whereas life is the most Desirable of all Sublunary Enjoyments and Health so Invaluable a Blessing that without it in some Degree Life is little Worth And that the Promoting Medical Knowledge among Physicians is the necessary and direct means to Restore Health and Even Preserve Life and is of great Importance as it will Render the Practice of Physic more safe and Serviceable to the Patient and at the same time yield more Satisfaction and Honour To the Profession.” etc.

But the memorial did not meet with favor in the eyes of the Lower House and when the question was put whether anything should be granted on this memorial it was resolved in the negative.

Local associations continued to be formed and further attempts at organization were made, which have left equally interesting documents, though in none is so profuse a use made of capital letters. The Society was finally incorporated in May, 1792, the act of incorporation providing for the formation of county societies, which county societies were empowered to choose by ballot certain persons who should represent them at a State meeting and be known as the Fellows of the Connecticut Medical Society, and the first meeting was held agreeably to

charter at the court-house in Middletown in October, 1792.

In the following year at a convention held at the house of David Bull, innholder in Hartford, a series of by-laws was adopted; after specifying the duties of the officers of the Society, it was ordained "that it shall be highly disreputable for any member to assume or hold the knowledge of any nostrum or pahn any medicine or composition on the people as a secret."

This was a subject which strongly exercised the feelings of the convention, for at a meeting in October of the same year it was further ordained "that all physicians and surgeons who pretend to any *nostrums* or *secrets* and are willing to communicate their knowledge to the public, that they may do it under the solemnity of an oath before some proper authority, therein declaring that they have revealed every simple and composition that they are possessed of relative thereto, and their whole method of administering the same without the least reservation. And that the nostrums or secrets shall be advertised in the several newspapers that circulate in the counties where they respectively reside."

In May, 1796, it was represented to the Society that "one of their members had gleaned up from the miserably remains of animal magnetism a practice consisting of stroking with pointed metallic instruments the pained parts of human bodies, giving out that such strokings will radically cure the most obstinate pains to which our frame is incident."

Such practices the Society denounced as barefaced imposition, and ordered their secretary to cite any member practising in such manner before them at the next meeting to give reasons why he should not be expelled for such disgraceful practices. No reference to the subject is made at the next meeting, but in the records of the second meeting appears the following:—

"Whereas, Doctor Elisha Perkins, a member of this Society, having obtained a patent from under the authority of the United States for the exclusive privilege of using and vending certain pointed metallic instruments (pretending that they possess inherent powers of curing many diseases, and that they were an invention of his own), which is directly contrary to rules and regulations adopted by this Society, interdicting their members the use of nostrums; thereupon *Voted*, That the said Perkins be expelled from said Society."

But the trouble in regard to nostrums was not terminated with the expulsion of the notorious Perkins. In 1803 a committee was appointed to prosecute all members who were patning upon the public nostrums or secret patent-medicines. At least two individuals made public the composition of secret remedies under oath and their declarations were published as provided in the by-law previously quoted. Dr. Samuel H. P. Lee, who preserved his

membership by the publication of the composition of New London bilious pills, took advantage of the publication to further advertise that the Society had given its sanction to his pill and the convention found it necessary to publicly reiterate the facts in the case and advise against their use. The public spirit of the profession is abundantly shown in these records which set forth in the condensed form of society records the interest in the establishment of a general hospital in New Haven, of a retreat for the insane, of the establishment of a uniform pharmacopœia, and of various kindred matters. In 1815 William Tully was appointed to write and read at the next convention a dissertation on "The Pernicious and Destructive effects of Ardent Spirits," and in 1817 the thanks of the Society were voted to Dr. Fowler for his dissertation on "The Deleterious effects of Ardent Spirits in the Hypochondriacal Temperament." In 1828 the Reverend Mr. Leavett addressed the Society on the subject of Temperance and the president, in behalf of the Society, pledged their coöperation in all reasonable measures on the subject, and a committee was appointed to report the measures proper to be taken to promote the objects of the American Society for the Promotion of Temperance.

The report of the committee is characterized by that discrimination which is to be expected of a medical convention. After a series of remarks that to-day are platitudes it goes on to say: "It gives to diseases a character which they do not naturally possess; it renders those which are mild severe and those which are severe fatal. No medicine can withstand the progress of maladies which are aggravated by the habitual use of ardent spirits. No skill can divert them from a fatal termination. It is therefore important to us, as we value the character of the medical profession, that we unite our efforts to remove this opprobrium, and as we love our country that we labor to conquer this its greatest and most dangerous foe. . . .

"The cause of temperance is not to be promoted by intemperate measures; nor will the abuse of ardent spirits be counteracted by indiscriminately opposing their use in those cases of disease in which their utility has rarely been called in question."

The resolutions passed on this occasion were published by the Society in the public papers and doubtless had all the influence the convention desired.

The interest the Society took in the subject of medical education shows itself on almost every page of the records. One cannot fail to be impressed by the constant increase in the requirements for a degree. One of the earliest of the honorary prize questions "proposed for discussion to the *faculty* or *literati* of the State of Connecticut or elsewhere" was an inquiry into the most eligible mode of increasing and propagating medical knowledge in the State of Connecticut. Some of the votes show

a minute interest that is almost amusing. In 1800 it was voted that the by-law prohibiting the examination of a candidate until he arrives at the age of twenty-one years be dispensed with in the case of Charles Rogers who is bound on a voyage to sea.

Something seems to have been attempted in the way of collective investigation, for in 1806 it was voted that it be recommended to the several members of the Medical Society through the State that they keep a commonplace-book wherein they shall minute down the most prominent symptoms of disease (either at the bedside of their patients or at home after the duties of the day are over), the medicines prescribed and their effects, the object aimed at in the prescription, and whether the intention was answered by the operation of the medicine prescribed, with such other remarks on the case as shall occur to the prescriber; and that these be transmitted to the secretary by the first day of October or of the month preceding any adjourned convention, to be had before the succeeding convention. Nothing seems to have been done further in the way of such investigation, however.

Such are some of the points of interest in these records of which many more remain unmentioned. Their publication is a valuable addition to the medical history of the country and the example of the Connecticut Society should stimulate other societies to take equal pains to preserve their memorials of the past.

#### PROFESSOR HYRTL'S JUBILEE.

THE veteran anatomist, Professor Hyrtl, who from 1817 to 1874 was one of the brightest stars of the constellation of the Vienna University, celebrated, on March 24th, the fiftieth anniversary of his graduation as a doctor. He received delegations and compliments from his former colleagues and from the present students who knew him only by reputation. Speeches were made, cheers were given, and the event was celebrated with enthusiasm. As a crowning honor, a deputation from the Vienna Doctoren-Collegium brought a magnificent document, his diploma as an honorary member of their body. This compliment has been paid only to Prince Charles Theodore, of Bavaria, and to Professor Virchow. Let us hope that the distinguished anatomist may long wear the laurels he has so laboriously gathered.

Hyrtl was born at Eisenstadt, in Hungary, near the close of 1811. He took his degree at Vienna in 1835, and only two years later was appointed Professor of Anatomy at Prague. He held this position for ten years, when he resigned to accept the professorship at Vienna. From then till 1874, his life appears to have been one of incessant work and rich in brilliant results. Since his resignation he has lived in quiet retirement at Perchtoldsdorf.

Hyrtl's influence on anatomy has been a great one.

The cause of it is to be found in his exceptional constitution, at once a man of talent and a genius, a worker and an enthusiast. Learned in the science as a professor should be, his technical skill excited general admiration. Injections may be said to have been his specialty, and notably corrosion preparations. He published his famous work on human anatomy in 1846, which we believe has passed through seventeen editions. His work on the art of dissection, which included many instructions for various preparations, is well known, but perhaps his Topographical Anatomy is the most familiar to the profession in this country. It would be hard to say what it does not treat of. It contains quotations in various languages, ancient and modern, ranging from grave to gay, from Roman classics to negro melodies. Applications of all sorts, surgical and physiological, abound. Bitter sarcasm and witty retort are brought into play in various controversies. Those, however, who would judge Hyrtl as an anatomist by this book would do him injustice. His vast knowledge is shown by his numerous contributions to the Proceedings, and to the more elaborate Memoirs, of the Academy at Vienna during the period of his professorship. Most of these papers treat of comparative anatomy. He was particularly devoted to fishes, of which he had, we believe, a fine collection. The papers in the Memoirs are most beautifully illustrated with plates, in which the vessels are colored. Among these papers we would mention a series of five contributions to comparative angiology containing numerous plates, among which those of the arteries of sloths and ant-eaters are particularly striking. A later paper on the arterial system of rays has a plate showing an injection of the brain that is truly wonderful. Still later is a paper on vascular plexuses (*wundernetze*) in birds and mammals, showing great research. Among more recent papers is the well-known one on the pelvis of the kidney in man and mammals. Two monographs widely known are that on the placenta, a description of injections of placentae of various shapes and arrangements, and the work on corrosion preparations, in which he describes at length his methods and dwells on the points of anatomy which they show. Among his short contributions to human anatomy and physiology we should name a paper on the coronary arteries and their relation to the aortic valves, one on trochlear processes of occasional occurrence in human bones, and his demonstration of two temporal ridges.

Great changes in the study and teaching of anatomy have occurred since he began his career. Among new methods of demonstration the most important is that of frozen sections, and not least the preparation of flexible muscular preparations. But greater forces than those of mechanical ingenuity have been at work. The great improvements in the microscope have immensely widened the field of anatomy. If we judge correctly there will soon be

new field in which much is to be learned, intermediate between the macroscopic and the microscopic, one in which the arrangement of muscular bundles, the relations of vessels and fasciae, will be studied on sections with powers magnifying only from ten to twenty diameters. Rüdinger has done good work in this branch and should have more followers. Another and, in some respects, farther-reaching influence has been that of the theory of evolution. Anomalies formerly looked at simply as curiosities, except when they had a distinct surgical bearing, became interesting as representing in one genus or species, as a variation, arrangements that are normal in others. Various other points, both of human and comparative anatomy, that, in old times, were little considered, now become most interesting from the conclusions to be drawn from them. This advance of anatomy brings a real danger with it, namely, that its scientific aspects should encroach on the attention that is due to practical details. Our medical schools must strive not to send forth scientific *dilettanti*, but graduates whose medical and surgical knowledge rests on the sure basis of anatomy. A great service that Hyrtl rendered was to insist on the practical applications of anatomy. With the advance of all the ramifications of medicine the field of applied anatomy will enlarge, and, even by the close of this century, the change will be immense from its condition in 1847, when Hyrtl was called to the chair at Vienna, but his influence will not have passed away.

#### THE SURGERY OF THE GALL-BLADDER.

THE recently instituted French Surgical Congress, of which our Paris letter gives an interesting account, has just concluded its first meeting and during its sessions listened to two papers on Cholecystotomy and Cholecystectomy, the operations of simple incision and entire removal of the gall-bladder. Each operation as a remedy for the diseases of the gall-bladder, particularly those due to the presence of gall-stones, has its advocates. Puncture of the enlarged gall-bladder by trocar and cannula in cases where adhesions had already taken place was advised by Petit as early as 1774. He also proposed the enlargement of the puncture by the knife when gall-stones could be felt by a flexible sound passed through the trocar, and some modification of the operation proposed by him has been repeatedly done. The entire removal of the gall-bladder is of much more recent origin. The exact indications for each operation have not been accurately determined, though the fact that the gall-bladder is a proper field for surgical interference is fully established.

The existing state of opinion on the subject seems to be well shown by the two papers read at the French Congress.

The paper of M. le Dr. J. Thiriar, of Brussels, on

surgical interference in certain cases of biliary lithiasis, is briefly to the following effect: The extirpation of the gall-bladder, as proposed by Herlin and Chaigneau, had not been performed on a human subject when Langenbuch, of Berlin, in 1882, operated on a patient with biliary calculus. Since then seven cases have been recorded. Five operations have been performed by Langenbuch, and two by the writer. Five radical cures have been obtained, and M. le Dr. Thiriar considers the two fatal cases seen by Langenbuch as resulting from accidents not connected with the operation.

These achievements of modern surgery have encountered, up to the present time, numerous critics who have opposed the application of surgery to the gall-bladder on various grounds, both physiological and pathological, which can be epitomized as follows:—

(1) The necessity of the gall-bladder to the digestive process in the human subject.

(2) Calculi can form elsewhere than in the gall-bladder.

(3) Cholecystectomy is too severe and dangerous an operation.

(4) The formation of a biliary fistula (Cholecystotomy) ought to be preferred to Cholecystectomy.

It is clearly shown that the gall-bladder is not indispensable to the regular performance of digestion in man. This organ is absent in many mammals, and is not infrequently found in the human subject completely occluded and atrophied.

Even if it must be granted that the formation of calculi is not wholly confined to the gall-bladder, it is an exceedingly rare occurrence, certain pathological conditions excepted, which can induce the formation of concretions in the biliary canals and ducts. Also the existence of these pathological conditions (carcinoma—obstruction of the biliary passages) form an express contra-indication for cholecystectomy.

Cholecystectomy is evidently a delicate and difficult operation to perform, but considering the slight importance of peritoneal injuries inflicted in accordance with antiseptic rules, M. Thiriar regards, of all forms of laparotomy, the extirpation of the gall-bladder as the least severe and least dangerous. It is an operation admissible in cases of biliary calculi which have resisted medical treatment and cause severe crises.

That while cholecystotomy, as done by Lawson Tait, is easier to perform, still it has the disadvantage of resulting in a biliary fistula with all its dangers, and it does not remove the organ in which the calculi are produced, or prevent their re-formation.

M. le Prof. Jules Boeckel, of Strasbourg, drew the following conclusions in a paper upon "The application of cholecystotomy to the biliary calculi":—

The seriousness of the operation of cholecystotomy depends upon the presence or absence of biliary fistula.

When a fistula exists, and the presence of one or more calculi has been demonstrated, the operation is indicated.

The operation is very simple and not especially dangerous where adhesions exist between the gall-bladder and the parietes of the abdomen, and, under antiseptics, does not yield a large mortality.

When, however, there is an absence of a fistula or adhesions the operation is very grave.

If a tumor of the gall-bladder exist which when aspirated reveals the presence of biliary calculi, the operation seems indicated to M. Boeckel.

The diagnosis well established, the operation ought to be done early to avoid the grave accidents which may follow delay.

In conclusion M. Boeckel remarks that the actual state of our knowledge does not permit us to decide between the two operations. Additional experience is needed to solve the problem.

#### MEDICAL NOTES.

##### BOSTON.

— Since our issue of last week three more cases of smallpox have occurred in Boston. All have originated at the West End, but no connection can be traced with any of the foregoing cases, except in one instance. A girl who was sent to the Smallpox Hospital, April 13th, was living with a sister who had been fully exposed, and who had never been vaccinated. The latter was vaccinated that same day. On the 20th the vaccine inside attained its acme, and on the 23d the girl developed a mild case of varioloid. There are now five cases in the hospital, of which three are practically convalescent. The other two, neither of whom had been vaccinated, are very sick with the confluent form of the disease. The total number of cases in the present epidemic has been six. Free public vaccination is now being carried on.

##### NEW YORK.

— A conference of representatives of the boards of health of New York, Brooklyn, Boston, Philadelphia, Baltimore, and New Haven, was held at the Fifth Avenue Hotel, April 23d, for the purpose of discussing quarantine matters generally and uniting upon uniform regulations for the prevention of the introduction of cholera into this country. Among other things, the admission of rags from foreign ports was taken up and fully discussed, and it was concluded to establish a close quarantine against them; allowing none to be landed until after having been thoroughly boiled or steamed by the superheated steam process. The sulphurous-acid disin-

fection of rags was conceded to be ineffectual, and the conference decided against it. The opinion was incidentally expressed that one principal reason why small-pox had been of such infrequent occurrence of late in New York was on account of the stringent regulations requiring all old rags to be disinfected.

— At a meeting of the State Board of Charities, held April 16th at Albany, a resolution was passed to the effect that, in view of the frequent prevalence of diseases, due to local causes, and the possible appearance of cholera during the coming season, the managers and officers of charitable and reformatory institutions throughout the State should be requested to make a critical examination of the institutions under their charge, for the purpose of determining whether they are in all respects — but especially as to sewerage, plumbing, water-supply, and the proper disposal of filth — in the highest possible sanitary condition, to the end that these establishments may, in the emergency contemplated, prove healthful restorative agencies, instead of centres for the propagation of disease, as is otherwise possible.

— The bill providing for a free park at Niagara Falls has finally passed both houses of the Legislature.

#### Correspondence.

##### THE FIRST MEETING OF THE FRENCH CONGRESS OF SURGEONS.

PARIS, April 12, 1885.

*Mr. Editor.*—The French Congress of Surgeons, — so called, — whose first meeting terminates to-day, is not, strictly speaking, *French*. Its foundation and aims have a broader purpose than the gathering of merely French surgeons. This purpose is to bring together once yearly not only surgeons of France, but of all countries, whose language is French — Belgium, Switzerland, Canada, etc., indeed of any country, the sole condition being that all papers shall be read and discussed in the French tongue. The Congress owes its birth to Professor Demons, of Bordeaux, who, early last year, addressed a note to the Society of Surgery, proposing the creation of a Congress of Surgeons. This proposition was referred to a Committee, composed of Trélat, Verneuil, Chauvel, Horteloup, and others, and this body finally accomplished the foundation, opened a list of members, and found the scheme eagerly adopted. The chief reasons for creating the Congress were: (1) Since the destruction by Lister and Eschmarch of the two *bête-noirs* of surgery — purulent infection and hemorrhage — provincial surgeons, who heretofore, in serious operations, have called to their aid surgeons of the metropolis, have begun independently to venture boldly into the domain of surgery; and such has been the growth of skill and experience that a better means for the interchange of intelligence than that afforded by the Section of Surgery in the French Medical Association has become necessary. Further, provincial surgeons seem to be in danger of passing from the extreme of timidity to that of temerity. This, at any rate, suggests the value of an annual congress at which the results of this greatly increased surgical activity may be gathered, discussed, and perhaps judged. (2) The publications of the

Congress will open a far larger channel of communication with the medical public; for, subjects read and discussed will not be consigned to, and hidden in, archives or in journals not widely read, but will be so published as to make the authors and disputants quickly and widely known.

The number of members already inscribed is 193, of whom fifty-four are founders. The latter include surgeons of Paris and many departments of France, also of Strasbourg, Bâle, Geneva, Brussels, Havana, and Copenhagen. In the general list are also surgeons from Russia, Italy, and Holland. The Congress will meet in Paris annually, during Easter week, in the Amphitheatre of the *École de Médecine*. The present meeting proves that the members are deeply interested. The scheme is a broad one, and, apparently, the importance and influence of the Congress will have a rapid growth.

By-laws require that members who wish to present papers, or rather communications, for they are very brief, shall make it known to the Secretary before January 1; and, at the same time, send a concise *résumé* which will be published in whole, or in part, in the programme distributed before the opening of the Congress. The forenoon sessions are devoted to communications, and discussions upon subjects given out by the "Permanent Committee." The afternoon meetings are given to "diverse communications." No reader is allowed to exceed fifteen minutes without permission of the President, who has the power to add ten minutes. Beyond this period he must consult the Assembly. In discussion, the limit for each speaker is five minutes which the President may increase to ten. The same speaker (disputant) may not occupy more than fifteen minutes of one session without consent of the meeting.

All manuscripts are to be given to the Secretary, otherwise only a *résumé* will be published. Members who wish to take part in discussions are requested to notify the Secretary in advance. They are called in the order of their inscription.

At these meetings, both morning and afternoon, the amphitheatre was filled with a very attentive audience. The President of this Congress was Professor Trélat, of Paris; Vice-President, Professor Ollier, of Lyons. At the long presidential table sat also Eugène Boeckel and Koehle, of Strasbourg, Socin, of Geneva, Verneuil, of Paris, Tilanus, of Amsterdam, and Chauvel, of Paris, six in all, who formed the body known as "*Présidents d'Honneur*." Each of these in turn presided, the actual President, meanwhile, taking place in the audience. At the opening of each morning session two of the "*Présidents d'Honneur*" were announced to act at the meetings of that day. This struck me as a very graceful way of honoring prominent surgeons, and at the same time a wise means of relieving the actual President of constant duty. The board of officers which attends to all the affairs of the Congress, including finances and publications, is called the "Permanent Committee," and is composed of seven members, including President and Vice-President. Every two years, two of the committee are to be replaced by a new election. The board has its own secretary who attends to all correspondence. On the right, and in front of the President, was a long table labeled "Secretaries." Here sat six secretaries facing the President. At each session one of these announced the programme of that meeting, and gathered papers as they were read. At the next session another secretary acted similarly, and thus by turns each one served, the remainder, meanwhile, taking notes of papers, and discussions for an official *résumé*.

On the President's left was a similar long table labeled "Press." Here sat six or eight reporters for medical journals. Both tables, as was also that of the President, were supplied in front of each man with a plenitude of writing material of every sort, the paper

having an official printed heading. The readers of papers and disputants sat at a small table a little lower than, and directly in front of, the President. The tables were uniformly covered with dark green cloth. Two or three servants, in plain livery, were always at hand, and so well instructed were they in their duties that they invariably knew, or did, or brought, or carried away the right thing at the right moment, without need of more than a word or a nod. The entire machinery of the Congress was simple, uncomplicated, and noiseless, and the manner of conducting meetings Spartan. When the hour arrived the chairman struck his bell and merely said: "*La séance est ouverte*." The secretary for that meeting then going to the reader's table announced the programme in detail. The President then said: "*La parole est à Monsieur X.*" and the reader came forward, and without saluting either President or audience, took his seat, and plunged into his subject. In no instance was a reader introduced by his title, not even of Doctor. The word was simply "*Monsieur*." When the reader reached his summing up, the President leaned forward and said: "You have four minutes," or two minutes, as the case was. If the quarter-hour allotted to each paper expired before the reader had concluded, the President announced the fact, and the reader was obliged to hasten and shorten. No exceptions were made, a venerable professor being pulled up with as little mercy as one of the youngest members. It was truly refreshing to observe this military promptness and decision. A much greater amount of work was thus accomplished. Every reader and disputant was applauded by the clapping of hands. Papers were read in groups of three or four, all relating to the same subject. They were at once followed by discussion (of five minutes to each man) by members who had already signified a desire to speak, and who were called upon, in order, by the invariable: "*La parole est à Monsieur X.*" and not one moment was lost. There was not a hitch nor a jar. Everything moved with the smooth quiet of an observatory clock. In the audience the utmost stillness prevailed, and attention to subjects seemed intense. Members were prompt in entering at the hour. Going, out of curiosity, into the courtyard of the school, to see whether members were chatting and gossiping during the hours of the session, I was surprised to find only two or three, and these young men, and perhaps not members. It was impossible not to recall the too frequent beggarly array of empty benches at such sessions of the annual meetings of our State Society, as are devoted to the reading of papers. A Fellow prepares his paper at great expense of time and study, and deserves a good hearing, but it cannot be denied, unless his subject be one of very marked and general interest, that his audience is mainly found in the readers of the *Boston Medical and Surgical Journal*. This is unfair and unjust, and I must confess to a feeling of mortification as I saw the vivid interest of the members of the Congress in every paper, whether it related to a simple matter like chronic abscess, to a subject of general interest to all surgeons, or whether it pertained to a special topic, as for example, ovariotomy or orthopedic operation. Indeed the warmest discussion of the meeting was, perhaps, on the proper treatment of the pedicle after ovariotomy. This, however, apparently is a matter which never will be settled.

At the opening of the final session, members were called upon to vote for president and vice-president for 1886, and again I was surprised by the absolute absence of complication. Upon the reader's table were two bronze vases, respectively labeled "President" and "Vice-President." At the word from President Trélat, members, already provided with two ballots, upon which they had written the names of their candidates, came quietly forward and deposited them folded in the proper vases. This was rapidly accomplished.

The President then emptied the ballots for president upon the table and counting them aloud: "One, two, three," etc., passed them one at a time to the presidential secretary who opened and deposited them in a pile. The number having been counted, the secretary returned the ballots, open, one by one to the President, who read the name upon each, tore each half across and replaced it in the vase. As he read the names of the candidates, the six official secretaries kept score, and as soon as the President had completed the reading of names, the result of the vote was ready for his inspection. He then read, "Monsieur A., so many votes. Monsieur B., so many votes," and finally announced as elected the man who received the largest number. The same procedure was followed with the other vase and the vice-president similarly elected. Here was no nominating committee, no hidden machinery. It may be that candidates had been suggested to the members (though this is very doubtful, simply because there were at least six candidates for president), but it was not done in committee. In taking the sense of the meeting by the raising of hands, the President counted the hands aloud: "One, two, three," etc. All was done quickly and quietly. Ollier, of Lyons, was almost unanimously elected president for 1886. The vote for vice-president ran closely between Engène Boeckel (there were two Boeckels present, cousins, both professors, both from Strasbourg) and Verneuil, of Paris. The latter was elected.

As to the comfort of the audience the less said the better. Probably at no period of the world's history did human ingenuity ever arrange more exquisitely uncomfortable seats than those of the Amphitheatre of the *Ecole de Médecine*. They consist simply of a horizontal plank, a dolefully narrow one and hard as a curbstone, supported by planks set on edge. No back whatever, and a straight fall for the leg, unless by good fortune you have no one in front. In that case you may rest your feet on the seat before you. There is just room to move between the seats and no stretch for the leg when sitting. You probably have at least one foot of each of the two men behind you in your coat-pockets. Your only revenge is to put your feet into the pockets or upon the coat-tail of the man in front. You must hold your hat and stick in your hands, and your overcoat upon your lap, for there is no other resource. Nevertheless, the audience sat patiently all day long, for six days, without a murmur. It was noticeable that there seemed to be a regulation dress of frock coat of black broadcloth, black trousers, and a silk hat. If there was an exception to this dress it was worn by an outsider. There was a room provided with abundance of stationery for members who wished to write. In another room one officer seemed to do the whole work of supplying tickets and information and of receiving fees, and during the hours of sessions he was perfectly idle, having no callers. A few instruments were exhibited in an ante-room, but no medical books, nor pills, nor medicines, nor extracts of beef, nor *chocolat de santé*, nor any of those scores of things which are displayed at home, and with which, one would think, we are so much plagued during the remainder of the year to make it quite needless to have them in our way at annual meetings.

The Congress was simply an earnest development and discussion of various surgical topics, and to these members were solidly devoted and, apparently, cared for nothing else. It was remarkable that readers, who made no use of their papers, or who spoke with no notes at all, were fluent of speech, never hesitated for words, and, evidently, were full of their subject-matter; for it was impossible to detect the slightest self-consciousness in any one of them. Ollier was the exceptional disappointment. Giving one the impression of a man of strong physique, his voice is weak and his utterance very indistinct, but he received very

respectful attention whenever he spoke. He has an attractive face, certain expressions of which vividly remind one of a well-known doctor of our own city.

In reading the list of members of the Congress, professors are found to be as relatively plentiful as titles in Germany. There are seventy-seven of them in a list of 193 members. This is, however, very significant of the intellectual quality of the Congress. In the prospectus sent out by the secretary occurs the pathetic remark: "It is not necessary to mention our *confères* of Alsace-Lorraine, whom we do not separate from the French."

As for the subjects treated at the Congress, they naturally were very diverse. Those proposed by the Committee were briefly: the aetiology and pathogeny of surgical infection; indications furnished to practical surgery by examination of the urine; the best dressing to employ in military surgery in the field; the cure of cold abscesses; operative indications in deep wounds of the abdomen. These were considered from various points of view during morning sessions. Coxalgia, ovariectomy, hernia, gastrotomy, fractures, artificial anus, operations on the eye, and many matters of which space does not admit mention, were the afternoon topics. Models, specimens microscopic, bony, etc., casts, and pathological preparations were plentiful. The Congress had a most successful beginning and we shall hear more of it. H. O.

## THE SANITARY CONDITION OF NANTUCKET.

Boston, April 20, 1885.

Mr. Editor.—Bearing in mind the necessity for brevity and the axiom that infinitely small quantities may be disregarded, I shall confine my reply to the first two of Dr. Abbott's criticisms of my communication of March 26th.

"(1) Dr. W. states: 'The report relies chiefly on its statistics for the conclusions reached.'" For the truth of this remark I refer to the report in which there are more pages devoted to statistics than sentences relating to the tour of inspection.

"(2) Dr. W. states: 'The State Board has compiled its statistics on the number of burials.' Very true and the same rule is applied to every city and town in the State." Thus Dr. A. defends the State Board, *not by saying its statistics are accurate, but by saying that they are not more inaccurate when applied to Nantucket than they are when applied to all other towns in the State.* Yet even in this defence the champion of the State Board is in error, as was shown in my former letter. Nantucket in 1810 had a population of 9,012; in 1880, of 3,727. This decrease of over 5,000 was largely due to emigration. Now, many of these emigrants died; their bodies were returned to Nantucket, and, as the report shows, their deaths were included in the record of the town's dead. Although, in life, these emigrants are not included amongst the population, yet in death they are included amongst the town's dead. As the fallacy of this reasoning does not seem perfectly clear to Dr. Abbott, let me illustrate it by a simple figure: A State official with a pen over his ear and an ink-bottle at his waist calls at a house in Nantucket and demands: "How many people live within?" The answer is "Two": that the four children of the household emigrated to the mainland ten years previous. The State official writes down in his book that two people live in the house, and takes his departure not to return until the following year. In the interval between his visits the four children of the family die on the mainland, let us say of one of those peculiar epidemics of diphtheria mentioned by the State Board in its footnote; their bodies are brought to Nantucket and they are buried from their father's house. When the State official returns he asks: "How

many burials have you had from this house during the past year?" The answer is "Four." Then the State official held up his hands in amazement: "Four people have died!" he exclaims. "This must be an extremely unhealthy house if two hundred per cent. of its inhabitants die in a single year!"

However ridiculous this may appear, yet it is exactly analogous to the reasoning of the State Board. Moreover, it is upon statistics so compounded that one fourth of Dr. A.'s defence is based. Nor does Dr. A. strengthen his position when he concludes his second objection by the remark: "Dr. W. carefully omits any

allusion to Captain Allen's admission that the bodies thus brought to Nantucket were *naties of the island*, and the obvious bearing of this fact upon the subject."

When the State Board and its statistics can only be defended by claiming that emigrants *inherit* typhoid fever, dysentery, and diphtheria from their native towns it seems to me that further argument is superfluous. In conclusion, I would simply add that Dr. A.'s defence is weak because of the weakness of his cause, as any one may convince himself by perusal of the report.

Yours truly,

HAROLD WILLIAMS, M.D.

# REPORTED MORTALITY FOR THE WEEK ENDING APRIL 18, 1885.

Deaths reported 2,414; under five years of age 818; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrheal diseases) 311, lung diseases 439, consumption 422, diphtheria and croup 421, scarlet fever 50, measles 38, diarrheal diseases 21, typhoid fever 20, cerebro-spinal meningitis 16, whooping-cough 15, malarial fevers 12, puerperal fever 12, erysipelas six. From diarrheal diseases, New York 10, Philadelphia five, Cincinnati three, New Orleans and Lawrence two each, Milwaukee and Providence one each. From typhoid fever, Philadelphia seven, Providence and Charleston two each, New York three, Baltimore, Buffalo, Milwaukee, Nashville, Springfield, and Haverhill one each. From cerebro-spinal meningitis, Buffalo three, New York, Philadelphia, Baltimore, New Orleans, and Worcester two each, Milwaukee, Springfield, and Taunton one each. From whooping-cough, New York eight, Boston and District of Columbia two each, Philadelphia, Baltimore, and Worcester one each. From measles, Baltimore four, New York and New Orleans three each, Philadelphia one.

Two cases of small-pox were reported in Boston.

In 112 cities and towns of Massachusetts, with an estimated population of 1,112,550 (estimated population of the State 1,955,101), the total death-rate for the week was 20.15, against 21.77 and 20.80 for the two preceding weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,906,446, for the week ending April 14th the death-rate was 23.1. Deaths reported 3,937; infants under one year of age 937; acute diseases of the respiratory organs (London) 178, measles 173, whooping-cough 130, fever 15, scarlet fever 33, diarrheal 26, diphtheria 27, small-pox (London 26, Liverpool and Manchester two each, Birmingham and Leeds one each) 32.

The death-rates ranged from 15.7 in Leicester to 40.4 in Sunderland; Birmingham 20.2; Birkenhead 21.9; Bradford 17.8; Hull 21.3; Leeds 21.9; Liverpool 21.4; London 21.7; Manchester 28.9; Newcastle-on-Tyne 33.7; Nottingham 130; Sheffield 25.2. In Edinburgh 17.1; Glasgow 31.6; Dublin 33.6.

For the week ending March 28th in the Swiss towns there were 52 deaths from consumption, lung diseases 31, diarrheal diseases 11, diphtheria six, small-pox five, measles four, typhoid fever and scarlet fever each three, whooping-cough two. The death-rates were: at Geneva 1.52; Zurich 9.7; Basle 21.9; Berne 39.3.

For the week ending April 14th in the Swiss towns there were 41 deaths from consumption, lung diseases 35, diarrheal diseases 12, diphtheria and croup seven, typhoid fever seven, measles three, whooping-cough two. The death-rates were: at Geneva 11.2; Zurich 8.7; Basle 29.3; Berne 17.0.

The meteorological record for the week ending April 18th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending	Barom- eter.	Thermometer.		Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall. Inches.

<sup>2</sup> Clearing up.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM APRIL 18, 1885, TO APRIL 24, 1885.

McPARLIN, T. A., lieutenant-colonel and assistant medical purveyor, United States Army. Sick leave of absence extended three months on surgeon's certificate of disability. S. O. 88, A. G. O., April 17, 1885.

SMITH, JOS. R., lieutenant-colonel and surgeon, BULLINGS, JOHN S., major and surgeon, McELDERRY, HENRY, major and surgeon, detailed to represent Medical Department of the Army at annual meeting of American Medical Association, to be held at New Orleans, La., April 28, 1885. S. O. 91, A. G. O., April 21, 1885.

ROBERTSON, R. L., first lieutenant and assistant surgeon. Granted leave of absence for one month. S. O. 43, Department of Texas, April 16, 1885.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE WEEK ENDING APRIL 18, 1885.

YEMANS, H. W., assistant surgeon. Detailed as medical officer, Revenue Steamer "Corwin" during cruise, April 16, 1885.

BATTLE, K. P., assistant surgeon. When relieved to proceed to New Orleans, La., for duty. April 13, 1885.

BROOKS, S. D., assistant surgeon. Granted leave of absence for ten days. April 16, 1885.

#### DEATHS.

DIED, in Taunton, April 21, 1885, William Hathorne Gage, M.D., M.M.S.S., aged fifty-four years.

In Dorchester, April 22, 1885, Andrew Alexander, M.D., M.M.S.S., aged seventy-three years.

In Templeton, Mass., April 26, 1885, Joseph Cummings Hatchelder, M.D., M.M.S.S., aged seventy-six years.

#### BOOKS AND PAMPHLETS RECEIVED.

The Nature of Mind and Human Automatism. By Morton Prince, M.D., etc., etc. Philadelphia: J. B. Lippincott & Co. 1885.

Forty-second Annual Report of the Managers of the State Lunatic Asylum at Utica for the Year 1884. Transmitted to the Legislature January 13, 1885.

Does Tobacco produce Amblyopia? By Franklin Coleman, M.D., M.B.C.S. Eng., Baltimore, Md., Professor of Diseases of the Eye and Ear, Baltimore Polytechnic and Post-Graduate Medical School, etc., etc. (Reprint from the Maryland Medical Journal.)

The New York Post-Graduate Medical School and Hospital. Schedule of Lectures on Mechanical and Operative Orthopedic Surgery. By Prof. Milton Josiah Roberts. Part I. Orthopedic Technology.

Reports of the Trustees and Superintendent of the Butler Hospital for the Insane. Presented to the Corporation at their annual meeting, January 28, 1885. Providence, R. I.

Twenty-fifth Annual Report of the Medical Superintendent of the State Asylum for Insane Criminals, Auburn, N. Y., for the Year ending September 30, 1884.

Eudemie Goltfre or Thyroecole, being the Thesis for the Degree of Doctor of Medicine of the University of Durham, for which the Gold Medal of the Year 1884 was awarded, etc. By William Robinson, M.D. and M.S. London: J. & A. Churchill, 1885.

Annual Report of the Librarian of Congress, exhibiting the Progress of the Library during the Calendar Year 1884.

Preliminary Report on Disinfection and Disinfectants. Made by the Committee on Disinfectants of the American Public Health Association.

Lessons in Hygiene: An Elementary Textbook on the Maintenance of Health, with the Rudiments of Anatomy and Physiology, etc. Comprising also Lessons on the Action of Stimulants and Sedatives on the Brain and Nervous System. Adapted for Common Schools. By John C. Cutler, B.S., M.D. Illustrated. Philadelphia: J. B. Lippincott & Co. 1885.

Insomnia and other Disorders of Sleep. By Henry M. Lyman, A.M., M.D. Chicago: W. T. Keener, 1885.

A Practical Treatise on Nasal Catarrh and Allied Diseases. By Beverly Robinson, A.M., M.D. (Paris). Second edition, revised and enlarged. With 152 wood engravings. New York: William Wood & Co. 1885.

Minor Surgical Gynecology. A Treatise of Uterine Diagnosis and the Lesser Technicalities of Gynecological Practice, etc. For the use of the Advanced Student and General Practitioner. By Paul F. Mundé, M.D. Second edition, revised and enlarged. With 321 illustrations. New York: William Wood & Co. 1885.

Catalepsy in a Child three Years Old. By A. Jacobi, M.D., New York. (From American Journal of the Medical Sciences, April, 1885.)

On Idiopathic Anemia. A Report of three Cases, with Remarks, and an Analysis of the Cases hitherto published in America. By J. H. Musser, M.D. Philadelphia. 1885.

An Introduction to the Study of the Compounds of Carbon, or Organic Chemistry. By Iasi Remsen, Professor of Chemistry in the Johns Hopkins University. Boston: Ginn, Heath & Co. 1885.

Operative Surgery in the Calcutta Medical College Hospital; Statistics, Cases, and Comments. By Kenneth McLeod, A.M., M.D., F.R.C.S. Eng. London: J. & A. Churchill, 1885.

The Microscope in Botany. A Guide for the Microscopical Investigation of Vegetable Substances. From the German of Dr. Julius Wilhelm Behnke. Translated and edited by Rev. A. B. Hervey, A.M., assisted by R. H. Ward, M.D., F.R.M.S. Illustrated. Boston: S. E. Cassino & Co. 1885.

Topographical Anatomy of the Brain. By J. C. Dalton, M.D., Professor Emeritus in the College of Physicians and Surgeons, New York, and President of the College. Vol. III. Philadelphia: Lea Brothers & Co. 1885.

Les Pansements et la Mortalité Epidémique et Contagieuse. Par le Professeur Leon Le Fort. Paris: Felix Aram, Editeur.

## SUPPLEMENT.

THE AMERICAN SURGICAL ASSOCIATION.<sup>1</sup>

THIRD DAY. — THURSDAY MORNING SESSION.

## THE HEALING OF ARTERIES AFTER LIGATURE.

By J. COLLINS WARREN, of Boston.

The speaker had for a number of years interested himself in studying the process of repair in arteries. The changes which occur in arteries after ligation may be not inaptly compared to those which occur in long bones after fracture. In both we find an external and internal callus, the former having only a provisional existence in the case of arteries, and subsequently giving place to a ligamentous union of the divided fragments, the latter undergoing such changes in the latter stages of the process that the canal or lumen of the vessel is imperfectly reestablished by the so-called "canalization" of the thrombus. In the meantime, the walls of the vessel, like the cortical bone, have undergone certain changes which enable them to participate in the final process of repair. When a large artery is tied in its continuity, the intima and a portion of the media are usually ruptured and the adventitia is gathered into a dense sheath around the constricted ends. The first noticeable change is the formation of the thrombi and the development of a granulation-like mass of cells about the ligature, which, if the ends have been cut short, is completely enveloped by them. When the injury done by the ligature is slight this new formation will be less in quantity. This granulation tissue extends some distance up and down the sides of the vessel in the periadventitial tissue, the round cells of which it is composed invading only the superficial layers of the adventitia. These cells follow the ligature as it cuts its way through and penetrate the spaces of the divided walls, make their way into the clot and contribute more or less to the development of the internal growth. This growth forms a callus-like ring at the seat of ligature, in size about twice the thickness of the vessel. At the end of a month, there are still evidences of such cicatricial mass of tissue, but at three months, a slender cord only unites the peripheral to the proximal end.

The changes in the proximal thrombus are well advanced on the fourth day. A budding from the ruptured ends of the media takes place, which spreads in various directions through the clot, attaching itself to the walls at various points, and leaving spaces or meshes still occupied with blood-clot. As these fragments of clot become disintegrated and disappear, spaces are left into which blood eventually circulates, and the so-called "canalization" of the thrombus is effected. By the fifteenth day, the new tissue has become very abundant. By the end of a month, only fragments of the thrombus remain, and the granulations now present themselves to the lumen of the vessel. There is a free communication between the spaces

of the granulation-like masses and the lumen of the vessel.

Certain changes in the meanwhile occur in the walls of the artery. There is a proliferation of the cells of the intima. This development is not sufficient to supply more than a small part of the internal callus. Whether the intima has been ruptured and the media exposed, there is an intimate connection existing between it and the new tissue. At an early stage of the process cells spring from the muscular layer and project into the thrombus; later, elongated spindle cells, like those forming the muscular layer, are seen projecting into the newly formed tissue. By the end of the second week the media and adventitia retract, leaving a space through which vessels find their way and communicate with those from the lumen.

The cicatricial process is completed in three months. The external callus and thrombus have disappeared.

In this process lies the explanation of the immaturity of cicatrices of this kind from aneurismal dilatation, so common after wounds of vessels. The protective influence of the thrombus insures the development of a tissue closely resembling the three layers of the vessel wall, and having all the powers of resistance which they possess. In the larger vessels of the human subject, where there is less muscular and more elastic tissue, the new muscular tissue is not so evident, but the connective tissue is increased in quantity, and extends a long distance into the lumen of the vessel.

The doctor also exhibited a number of specimens and microscopic preparations illustrating his remarks.

## DISCUSSION.

DR. N. SENN, of Milwaukee, had been much interested in the reading of the paper. He would, however, attribute the external callus which had been described to the force which was used in the ligation and to the neglect of antiseptic precautions. If only sufficient force was employed to bring the internal coats of the artery in contact this would not be observed. He would carry Dr. Warren's comparison of the healing of an artery to the healing of a bone after fracture still farther. If the ends of a fractured bone were kept at perfect rest and in apposition there would be but a slight amount of callus, while if these precautions were not taken the amount of callus would be greatly increased. While he hoped that the view of Dr. Warren in reference to the formation of muscular tissue in the cicatrix would be confirmed, yet he must say that it was against analogy. We always expect muscular tissue, when divided, to unite by means of connective tissue. The reason that aneurism was so infrequent after ligation, he thought, was the development of connective tissue in the vessel. As a result of the rest imposed upon the artery by ligation the muscular tissue underwent fatty degeneration and was absorbed, its place being filled by

<sup>1</sup> Concluded from page 419.

unyielding connective tissue. He suggested that the muscular cells seen by Dr. Warren might be the cells of preëxisting muscular tissue displaced by the contraction of the cicatrix.

Dr. WARREN, in closing the discussion, said he had exhibited those specimens and illustrations which showed the changes in the most marked degree, but he had specimens in which the force exerted had not been excessive in which the same external callus could be seen, although to a less marked extent.

Dr. Senn had overlooked the difference between striped and unstriped muscular tissue. The former was much more complex than the latter, and healed, as had been stated, by the formation of connective tissue. In the unstriped variety, however, it was different, and in support of his assertions he referred to the great development of unstriped muscular tissue which takes place in pregnancy and in myoma of the uterus.

#### SOME POINTS IN THE SURGERY OF HYPERTROPHIED PROSTATE.

By J. W. S. GOULEY, M.D., of New York.

He first took up the mode of determining the amount of obstruction and described an instrument which he had devised for this purpose. A large portion of the paper was occupied with a consideration of the use of catheters. The catheter to be used should always be a soft one. Hard instruments were condemned. In overdistension of the bladder from retention, care should be taken to empty the bladder gradually, and it was recommended that, after a portion of the urine has been removed, a solution of boracic acid be thrown into the bladder.

He also spoke of the use of hydraulic dilatation in cases of contracted bladder, describing at length the plan to be pursued.

The speaker then took up the subjects of prostatomy and prostatectomy, and considered the indications and contra-indications of these operations, and showed the instruments for their performance. He claimed to be the first one who had reached the prostate through the perinaeum and incised it for enlargement.

#### DISCUSSION.

Dr. GROSS and Dr. PREWITT endorsed these views.

Dr. MOORE, in referring to the treatment of irritable bladder in these cases, recommended the moral treatment which consists in advising the patient to resist as long as possible the desire to urinate. In this way the intervals between the acts of urination can be gradually increased. The doctor mentioned four hours as about the proper interval.

Dr. GUNN and GOULEY had also practiced this plan with success.

#### AFTERNOON SESSION.

Dr. ERNST, of Boston, presented a number of culture tubes in which he had cultivated micrococci from various surgical affections and described the methods employed. He explained that the growth of the micrococci in the culture medium lead to changes in color according to their nature. The two most common colors were yellow and white.

He had observed a citron-like color which had not been noted before. This was produced by fluids removed from an epithelioma of the leg. The doctor stated that his experiments had been made to confirm those of Rosenbach. He intended to pursue the experiments and to perform during the coming months a number of inoculation experiments.

Dr. S. W. GROSS, in view of the great importance of the subject, moved that Dr. Ernst be invited to prepare a paper giving the results of his experiments and to read it at the next meeting of the American Surgical Association.

The motion was adopted.

#### AN EXPERIMENTAL AND CLINICAL STUDY OF AIR EMBOLISM.

By N. SENN, M.D., of Milwaukee.

This was an exhaustive paper giving the results of a number of experiments.

The following *résumé* was then presented:—

(1) The presence of adventitious air in the vascular system during life gives rise to air embolism.

(2) Each air embolus constitutes a mechanical source of partial or complete obstruction to the flow of blood in the vessel in which it is located.

(3) Aspiration during the inspiratory movements of the chest is the direct or exciting cause of the ingress of air into a wounded vein or sinus.

(4) Elevation of the head is the sole predisposing cause of the entrance of air in wounds of the superior longitudinal sinus.

(5) In veins, the predisposing causes consist in

(a) Elevation of the part wounded;

(b) Pathological or anatomical conditions which prevent collapse of the vein when it is wounded.

(6) Insufflation of a fatal quantity of air into a vein produces death by

(a) Mechanical overdistention of the right ventricle of the heart and paralysis in the diastole;

(b) Asphyxia from obstruction to the pulmonary circulation consequent upon embolism of the pulmonary artery.

(7) Insufflation of the same quantity of air into arteries is less dangerous than when introduced into veins. When death is produced in this manner it results from

(a) Acute cerebral ischemia;

(b) Secondary venous air embolism;

(c) Intense collateral engorgement of the vessels of the brain and spinal cord, the manner of death being determined by the amount of air injected and the direction in which the injection is thrown, as well as the time which has elapsed between the operation and the fatal termination.

(8) Air injected into arteries is readily forced through the systemic capillaries into the venous circulation and right side of the heart by the powerful contractions of the left ventricle.

(9) An air embolus of the pulmonary artery is relieved in a comparatively short time, provided the contractions of the right ventricle continue unimpaired for a sufficient length of time to force the air through the pulmonary capillaries into the general circulation.

(10) The prophylactic treatment consists in

proximal or double compression, or ligation of the vein which is endangered by the operation.

(11) The indirect treatment has for its objects :

(a) Prevention of the admission of air.

(b) Administration by inhalation or hypodermatic injection of cardiac stimulants.

(c) Venesection.

(12) The direct or operative treatment by

(a) Puncture and aspiration of the right ventricle.

(b) Catheterization and aspiration of right auricle, which is proposed to obviate the direct cause of death by the removal of air and spumous blood, thus relieving directly the overdistention of the right ventricle and at the same time to guard against a fatal embolism of the pulmonary artery.

(13) The results obtained by experiments on animals warrant the adoption of the operative treatment of air embolism in practice as a last resort, in all cases where the indirect treatment has proved inadequate to meet the urgent indications.

The Association then went into executive session.

#### THE FOLLOWING OFFICERS WERE ELECTED.

President, Dr. Moses Gunn, Chicago. Vice-Presidents, Christopher Johnson, Baltimore, Md., and Thomas R. Russel, Baltimore, Md. Secretary, Dr. J. R. Weist, Richmond, Ind. Recorder, Dr. J. Ewing Mears, Philadelphia, Pa. Treasurer, Dr. J. H. Brinton, Philadelphia, Pa. Dr. L. McLane Tiffany, of Baltimore, was added to the Council.

The next meeting is to be held at Washington on the Wednesday preceding the meeting of the American Medical Association. Chairman of the Committee of Arrangements, Dr. J. S. Billings, Washington, D. C.

#### MEMBERS ELECTED.

Dr. J. Edwin Michael, Maryland; Dr. Roswell Park, Buffalo, N. Y.; Dr. W. H. Carmalt, Conn.; Dr. J. Ford Thompson, Washington, D. C.; Dr. Theodore R. Varick, Jersey City, N. J.

#### THE FOLLOWING HONORARY MEMBERS WERE ELECTED.

Sir James Paget, Mr. John Eric Erichsen, Sir Joseph Lister, Prof. Thomas Annandale, Edinburgh, Prof. Fredric Esmarch, Kiel; Professor Von Langenbeck, Berlin; Professor Volkman, Halle; Professor Czerny, Heidelberg; Professor Billroth, Vienna; Professor Von Nussbaum, Munich; Professor Verneuil, Paris; Professor Ollier, Lyons.

#### FOURTH DAY.—FRIDAY MORNING SESSION.

##### DISCUSSION OF DR. SENN'S PAPER.

DR. WARREN said that the condition known as air embolism was more frequently met with in obstetrical than it was in surgical practice. He described a case reported by Dr Draper, in which an attempt was made to produce an abortion by the injection of air into the uterus. Fifteen minutes after the injection had been made the woman gave a few gasps and died. At the post-mortem examination, the heart was found distended with air and air was also found in the ascending vena cava and in the arterial capillaries. He considered that more was to be ex-

pected from prevention than from cure, for it would be rare that the surgeon would be provided with the necessary instruments or have the time to use them when the accident occurred.

DR. GORDON, of Portland, Maine, was introduced by Dr. Moore, and described a case which had come under his observation. In a case of pelvic abscess, he had twice removed the pus with an aspirator. On the third occasion aspiration was again proposed. The instrument employed was one which compressed or rarefied the air according to the manner in which it was used. The assistant, in arranging the instrument, so attached it that the air in the bottle was compressed. The aspirating needle was plunged into the abscess and the connection made. The woman gave a scream, placed her hand over her heart and in a minute was dead. In reply to a question, the doctor stated that he was unable to obtain an autopsy.

DR. NAXCREDÉ stated that it had been shown by experiment that the free circulation of blood through the capillaries was dependent upon a proper density of the fluid and that symptoms similar to those of air embolism could be produced by altering the density of the blood by the injection of water.

DR. SENN had considered the cause of death to be paralysis of the heart from overdistention, and this was probably the case where large amounts of air were introduced, but in the cases met with in surgical practice the amount of air was not so large. The spumous blood thus formed could not pass through the capillaries, and ischaemia of the brain with want of blood in the respiratory centres resulted.

As to treatment, he considered the preventive the most important, and in operating, in a position where there was danger of the entrance of air, he always adopted certain precautions. Complete anaesthesia was insisted upon. In operating on the neck he took care that pressure was made on the cardiac side of the veins. The deep attachments of tumors in this region were ligated before the tumor was separated.

In the direct treatment he recommended artificial respiration in the recumbent position with the feet elevated, pressure being made on the femoral arteries. The use of atropia was advised for its effect in causing dilatation of the pulmonary capillaries, thus permitting the freer passage of blood.

DR. SENN, not being present to close the discussion, was given the privilege of submitting his reply in writing.

##### THE ETIOLOGY OF TETANUS.

DR. P. S. CONNER, of Cincinnati, submitted a paper on this subject, of which we give an abstract:

The cases placed under the generic head of tetanus may be divided into two classes, the one characterized by spasms primarily affecting the injured part, the other by spasms primarily located in the muscles whose nerves have origin in the medulla oblongata. There is little doubt that the disease is located in the central nervous system and scarcely more that it is essentially an exaltation of the reflex irritability.

It has not yet been determined whether the affection is brought about by the nerves, by the blood current, by extension of inflammation, by reflected irritation, by septic changes, or by the presence and

development of micro-organisms. These different views were taken up and the evidence in favor of and against them given.

The view commonly held is that it is a reflex neurosis. It is argued that peripheral irritation will give rise to movements affecting a whole extremity which are independent of the will; that nerve injury is often connected with cramps and jerkings of the limb; that the disease is most commonly seen in cases where crushing of nerves has occurred; that the affection usually follows injuries in which a part liberally supplied with sensitive nerves is involved; that it is so quickly developed as to be possible only through reflex irritation, and, lastly, that it can be experimentally produced.

This view cannot be adopted positively because our knowledge of physiology will not warrant us in believing that an irritation starting, it may be, in the foot will pass over all the intervening portion of the cord and produce an influence in its upper part. The infrequency of tetanus is also against its causation by nerve injury.

In regard to the statement that hand and foot injuries were most frequently followed by tetanus, it was stated that in the late war there were 16,000 foot injuries, with only fifty-seven cases of tetanus, while in 12,000 hand injuries there was not one case of tetanus reported. The disease more frequently follows injury to the palmar and plantar fascia than wounds of the more sensitive fingers and toes.

If the disease cannot be accounted for on any of the above theories, it must be attributed to changes in the quantity or quality of the blood-supply. Experiment has shown that overfilling or emptying of the bloodvessels will cause convulsions. These however, are not tetanic. We must then look to the quality of the blood-supply. It must be found in the presence of a septic element developed in the wound, or from a micro-organism from without. This theory is only rendered probable from reasoning and analogy. The absence of fever has been supposed to be opposed to the idea of its infectious nature. It can only be presumed that the irritant is developed in the secretions of the wound. It is difficult to explain the idiopathic cases on this or any other theory. There is a possibility of the chemical development of poison both in the fluids and in the decomposed tissue.

It was suggested that the liability of tetanus in injuries of the hand and feet was due more to the pent-up secretions than to nerve injury. The vessels of the nerve itself may be the channel through which the morbid material is carried, and the anatomical fact that a relation exists between the sensibility of the nerve and the number and closeness of its lymphatics may go far to explain why tetanus is so frequently associated with wounds of parts endowed with high sensibility.

It was concluded that the nature of tetanus was uncertain, although the balance of evidence seemed to be in favor of a septic origin.

#### DISCUSSION.

Dr. MOORE asked if Dr. CONNER had investigated the reason why tetanus so frequently followed injuries inflicted with the toy pistol.

Dr. CONNER had attributed these cases more to

the nature of the wound leading to the discharges being retained, than to any poisonous compound in the powder employed.

Dr. PREWITT thought that in all probability tetanus was not produced by a ferment multiplying in the blood, but by a poison which produced its effects by a constant introduction of increased quantities into the blood. He was inclined to adopt the view presented by Dr. CONNER.

Dr. MEARS referred to the importance of this disease, and the great desirability of more thoroughly understanding its nature as a preliminary to its more successful treatment.

He could not understand the infrequency of the disease after hand and foot injuries during the war. Many cases would naturally have been expected in the conditions under which the soldiers were placed.

Dr. WEIST reported one case of fatal tetanus following an injury to the finger of a soldier from Maine. He also reported three cases which he had seen result fatally during the past two years. In these cases the affection followed crushing injuries of the hand.

Dr. TIFFANY said, in reference to tetanus following the use of the toy pistol, that he had known of fourteen cases resulting fatally within a period of ten days. He had the powder used in the pistol examined, but with negative results. He stated that tetanus was extremely frequent among negroes and this led him to doubt that it was due altogether to reflex nerve irritation, for the dark race is not so liable to such affections as is the white race.

Dr. MEARS had also had the fulminate examined with negative results. He was inclined to attribute the liability of tetanus to follow such injuries to the fact that the cartridge is broken into pieces which penetrate the hand.

Dr. NANCYERDE referred to a number of cases which had come under his observation. He had seen but two recoveries. The cases which he had seen had usually followed trivial injuries. He referred to the many methods of treatment which had been adopted. He had seen most of them applied without beneficial result. In one case marked relief appeared to be afforded by nitrite of amyl.

Dr. PREWITT reported two cases in which tetanus had developed some time after the receipt of the injury. In these cases the treatment was the administration of bromide and chloral with five-drop doses of Fowler's solution every three hours continued for two weeks. In these cases there seemed to be a special tolerance to this remedy for one of the cases, that of a man who received an injury of the right arm; the tetanus was followed by paralysis of the flexor muscles of the left foot.

Dr. GUNN had seen many cases of this affection, most of them ending fatally. He had had three recoveries. In two the nerve was stretched and in the other amputation was performed and calabar had been administered. He stated that the most hopeful cases were those in which the tetanus developed some time after the receipt of the injury. This idea was formulated as follows: The fatality is in direct ratio to the acuteness of the attack.

Dr. BRIGGS considered predisposition a very important element in the causation.

Dr. CONNER, in closing the discussion, said that the more he had heard the more had he been impressed with the evidence in favor of the humoral theory. While he admitted the possibility of predisposition, yet the fact that these individuals had many times before received severe injuries was against this idea.

#### THE IMMEDIATE CURE OF FISTULA IN ANO.

by STEPHEN SMITH, M.D., of New York, was read by title.

#### A CASE OF CHOLECYSTOTOMY,

by C. T. PARKES, M.D., of Chicago, was read by Dr. MOSES GUNN.

The patient was a lady aged twenty-nine, who had suffered for some time with symptoms of hepatic trouble. The diagnosis of obstruction of the common duct was made. All forms of medical treatment having been tried without result an operation was performed. This consisted in making an incision over the position of the distended gall-bladder, aspirating it, stitching it to the abdominal incision, then opening it freely, and evacuating a considerable quantity of muco-biliary fluid. No stone could be detected at this time. Several days later seven small calculi were removed. The patient recovered from the operation without any bad symptoms. The condition was improved, but the bile still failed to flow into the intestine. One month later a second operation was performed, which consisted of extending the incision, and passing a sound through the cystic duct into the bowel. This was followed by decided benefit, the bile escaping into the bowel, and it still continues to do so. The fistula soon healed. Four months later she was attacked after exposure with pain similar to that which she had originally experienced. This was attributed to increased narrowing, preventing the free escape of bile, and an incision was therefore made, reopening the old fistula. This gave complete relief.

#### DISCUSSION.

Dr. MEARS insisted on the surgeon having a thorough knowledge of these affections, so that he might be able to make a correct diagnosis. He then enumerated the different conditions in which the operation described was indicated. He did not favor the exploratory operations in these cases, which had been suggested by some writers. The importance of instituting proper treatment to prevent the recurrence of the trouble was spoken of. If this was not done the operation would probably prove of only temporary benefit.

Dr. TIFFANY called attention to the difference between the behavior of a unilateral and that of a bilateral organ when its duct was obstructed. In the cases of the liver almost complete obstruction might exist for a long time without serious injury, while if there was obstruction in the kidney it would in a comparatively short time become disorganized.

Dr. PICKWITT, in speaking of the difficulties of diagnosis, described two cases in which the distended gall-bladder was distinctly felt on palpation. One was the case of a man seventy years of age who had never exhibited any symptoms of hepatic colic, who was suddenly seized with pain and collapse. On palpation the distended gall-bladder, containing

a number of stones, was distinctly felt. The patient never reacted from the collapse and the correctness of the diagnosis was shown at the autopsy.

#### PHOSPHOROUS NECROSIS OF THE JAWS.

By J. EWING MEARS, M.D., of Philadelphia.

The paper was based upon the treatment of sixteen cases. The subject was elaborately treated and a number of specimens, showing the portion of the jaws removed, was exhibited. In closing, the reader presented the following conclusions:—

(1) That phosphorous necrosis of the jaws is a local expression of the constitutional condition produced by the inhalation of the vapor of phosphorus and by particles of the agent taken into the system with the food by operatives in match factories who do not give proper attention to cleanliness of the hands.

(2) That the introduction of the agent into the system is, as a rule, very gradual, and in such small quantities as to avoid the production of symptoms of acute poisoning. That, in this way, the chronic toxic condition of the system is induced, characterized chiefly by disintegration of the red blood-corpuscles and fatty degeneration of the arterial coats.

(3) That the toxic condition precedes the development is shown by the fact that the disease does not attack operatives recently exposed to the action of the agent, but those who have been exposed for a period of years.

(4) That examination of teeth of operatives has shown that many who have a condition of caries, and that many who have returned to work immediately after the extraction of teeth, have enjoyed immunity from the disease, showing that the agent has not attacked the periosteal tissue thus exposed. (In one of the cases the disease did not appear until three months after labor in the factory had ceased.)

(5) That individuals vary in their susceptibility to the action of the poison: for this reason many suffer immediately with symptoms of acute toxic conditions, such as nausea, vomiting, etc., and are compelled to abandon work in the factories.

(6) That the conditions under which experiments have been made on animals to prove the absence of the disease until exposure of the periosteum and peri-alveolar tissue was effected were not similar to those to which operatives in match factories are subjected.

(7) That treatment of the disease in the primary stage in the manner outlined is efficient and prevents its progress.

(8) That the antidotal powers of turpentine have been established, both in neutralizing the effects of the poison upon operatives during their work and also in the treatment of the early stage of the disease.

(9) That the disease is to be prevented among operatives by the adoption of thorough methods of ventilation, stringent rules with regard to cleanliness and the free disengagement of the vapor of turpentine in all the apartments of factories in which the fumes of phosphorus escape.

Remarks in discussion were made by Drs. Moore, Nanerode, and Mears.

An apparatus for rapid anesthesia was exhibited by Dr. Mears. This he had devised in August, 1884. It consisted of a metallic mask fitting over the mouth and nose and connected by a tube with a bottle containing ether. The bottle is placed in a basin of warm water which causes the ether to be vaporized and it thus reaches the patient in a very concentrated form. If preferred, the bottle may be connected directly with the mask and the ether allowed to pass slowly on to the sponge within. In this way the escape of ether into the room is largely prevented.

The committee on publication were authorized to add the vignette of the late Prof. S. D. Gross to the seal of the Association.

The President-elect was then conducted to the chair and made a brief address, thanking the Association for the honor conferred upon him.

Notes of thanks were then extended to the retiring officers and the committee of arrangements, after which the Association adjourned.

#### ANNUAL MEETINGS OF THE AMERICAN SURGICAL AND OF THE "FRENCH-SPEAKING" SURGICAL ASSOCIATIONS.

THROUGH promptness on the part of our reporter, and by issuing a supplement of six additional pages, we are enabled to give the readers of the JOURNAL a full report in one issue of the annual meeting of the American Surgical Association, which was held in Washington last week from Tuesday to Friday inclusive. Such a report as that to which our readers' attention is called is in every way more satisfactory and of more genuine value than any telegraphic report of such an affair could possibly be, and, at the same time, the utmost possible dispatch in publication has been secured by the method adopted. By adopting the supplement, a device so commonly resorted to by our overcrowded daily contemporaries, our readers, and those participating in the proceedings of the Surgical Association, enjoy the advantages of a continuous report, covering from nine to ten pages of print, without injustice to other departments of the JOURNAL.

We are fortunately in a position, at the same time, to publish an interesting letter from a correspondent in Paris, giving a very graphic account of the late

meeting of the French Congress of Surgeons, by which a comparison can be made of the methods and results of the American and French-Speaking Associations — a comparison which cannot but result in favor of the French Association. It is evident that much may be learned from the arrangements contributing so materially to the success of the Paris meeting, and it is also evident that our Surgical Association, in common with other American associations and societies which it is unnecessary to particularize, might greatly improve the conduct of business and the character of the discussions of papers.

If the members had an early synopsis or summary in print of the conclusions reached by the writers of papers, the discussions would quickly and easily assume a directness and pertinency which they now lack, and the value of the papers submitted to discussion would increase in direct proportion to the reasonable expectation of a debate which would be an illumination to the subject and a compliment to the reader.

We shall doubtless have occasion to revert to this subject again during this present season of Annual Meetings.

## Original Articles.

## THE PRINCIPLES OF SANITARY PLUMBING.

BY J. PICKERING PUTNAM, ESQ., OF BOSTON.

A FIFTH step consists in increasing the number of reflecting surfaces, and in breaking up the long horizontal body by making it return upon itself in a quadrangle, as shown in perspective in Fig. 14. In this form of the trap we have still further greatly increased the reflecting surfaces and the power of resistance to siphonic action, and we are now able to dispense with reflecting pockets, but we have obtained a trap exceedingly

Fig. 14. Fifth step.

difficult to manufacture, awkward in appearance, and troublesome to clean out in case of accident, as when a match or any such foreign substance is dropped into the waste-pipe and becomes lodged in a bend of the trap. This form of trap must be simplified so as to render it practical, without losing any of the advantages we have thus far arrived at.

Figs. 15 to 19 show the manner in which this may be done, and the arrangement forms the final step of our improvement. We have here retained all the reflecting surfaces; the horizontal body, which allows the air to pass above the water after a small quantity has been driven out, without disturbing the rest; and the slight contraction of the inlet and outlet pipes at their junction with the body of the trap. We have added a cylindrical cleanout cap of glass, and obtained an apparatus which can be readily cast in lead in moulds of iron. The quadrangular shape

Fig. 15. Sixth step. "Sault de" trap.

Fig. 16. "Sautas" trap.

of the horizontal body is retained, but the two parallel cylinders are brought together and merged

into a single cylinder having a central partition about two thirds of its length, or extending from one end to the edge of the cleanout cap, which at the other end forms about one third of the total length of the cylinder.

In ordinary use the waste-water passes through this trap in such a manner as to act to the best

Fig. 17. Body of trap.

advantage in scouring it. The partition wall in the centre of the body causes the water to scour each side in succession. Thus while in outward appearance the body resembles a small pot-trap placed horizontally it has in principle the self-scouring form of the S trap. It must be understood, however, that like the S trap it is only self-scouring when properly set, namely: with a free outlet from

Figs. 18 and 19. Glass cap and bridge.

the bowl somewhat larger than the inlet-arm of the trap at its largest part, or at its point of junction with the fixture. If set under a fixture giving a clear water-way of only one inch or of half an inch, this trap will not scour itself, nor will the waste-pipes with which the trap is connected. A good-sized washbasin holds, up to its overflow, about two gallons of water. This will escape through an average length of one and one-half inch waste-pipe, running full-bore and having a good fall, in about three seconds. Hence, through such a pipe the water rushes at a rate of more than half a gallon

<sup>1</sup> Concluded from page 409.

<sup>2</sup> This trap is manufactured by the "Sautas" Manufacturing Co., No. 4 Pemberton Square, Boston, Mass.

a second and fully scours the pipes. With lavatories constructed on this principle, the argument for trap ventilation based on the supposition that it is necessary to keep the branch wastes clean no longer holds good.

Let us examine now the action of the air and water in our trap under the influence of a very powerful siphonic action. We will suppose the trap to be placed in position under a fixture with the water standing in its normal condition up to the level of the outflow, as shown in Fig. 16. When, through siphonic action, a partial vacuum is created in the waste-pipe below the trap, the water in the inlet-arm of the trap descends under the influence of the atmospheric pressure on its surface tending to restore the equilibrium, until it reaches the dip of the trap. The air then being lighter than water passes into and through the body of the trap and drives a portion of the water, not already driven out, before it into the waste-pipe. The water remaining in the body falls back and maintains the seal. Subsequent siphonic action cannot remove this water for the following reasons: The water standing in the inlet-arm after its partial removal from the body of the trap by siphonic action, as described, is again lowered by a repetition of the action to the dip. Air again rushes into the body to fill the partial vacuum and passes into and through the water standing therein. This water, though increased in depth by that which enters from the inlet-pipe, is, nevertheless, shallow enough to give room for its passage. It projects upward a certain quantity of water in its passage, with greater or less violence, according to the strength of the siphonic action produced. This water strikes the under surface of the partition in the body, and is partly reflected backward by it, and partly follows the air-current toward the opening between the end of the partition and the cleanout cap. Owing to the greater weight and momentum of the water over that of the air, the water is reflected back, while the air passes on. A second reflection takes place against the surface of the cleanout cap. More water is thrown back, and a small remaining portion only succeeds in following the air into the passage above the partition. Of this small portion part again is reflected back by the upper inner curved surface of the horizontal body, and under very strong siphonic action a few drops may reach the last reflecting surface at the end of the body opposite the cleanout cap, whence it is once more arrested, and the air alone escapes into the waste-pipe. The spray falling upon the partition and upon the various reflecting surfaces collects at the bottom of the body and increases the depth of the seal. The greater cohesive and attractive force of the particles of water over that of air aids in the separation, since it causes a quantity of the former to adhere to the reflecting surfaces while the air escapes. This arrangement of the reflecting surfaces evidently also prevents loss of the water-seal by the momentum of the water descending from the fixture.

Although the seal is not excessively deep, yet the trap, owing to the considerable horizontal extension of its passages, contains a large enough body of water to protect it from the dangers of evaporation

and back pressure. The contraction of the inlet and outlet arms at their junction with the body of the trap renders it secure against self-siphonage. The form also renders loss of seal through capillary attraction impossible, as will be hereafter shown.

When used where trap ventilation is prescribed by law, this trap can, of course, be ventilated like any other. The vent may be applied at any part of the outgo, either at or below the crown. But since, unlike S traps, its seal cannot be destroyed by self-siphonage or momentum, the vent need not be applied at the crown. It may be applied anywhere below the crown far enough away to quite avoid the injurious effects of evaporation. Hence, ventilation does not produce the destruction to the seal that it does with other self-cleansing traps, and may be used with impunity. Trap ventilation is, nevertheless, in this case, as in most others, absolutely useless, and its installation is a total loss to the house-owner.

Having now explained the theory of the construction of the "Sanitas" trap, let us make a practical trial of its operation.

The first discharge of both closets, the soil-pipe extension being forty-five feet, will lower the seal considerably, say to a point below the centre of the glass, but subsequent discharges will have very little further effect upon it, and when the seal has been reduced to about an inch and a half, or in the very severest possible cases long repeated, possibly to an inch and a quarter or eighth, even the most powerful suction that can be applied with an apparatus used in practice will have no further appreciable effect upon it, even though the siphonic action be strong enough to destroy the seal of a fully ventilated S trap or of a six-inch pot-trap. Ordinary siphonic action will simply lower the water in the trap enough to permit the passage of air above it, leaving a seal of two inches or more permanently in the trap. The test which we are about to apply to this trap is severe enough to siphon out completely in a single second a fully ventilated S trap or a four-inch pot-trap.

*Discharge Z and J.* After this very severe test we find a seal left of one and one-half inch.

*Repeated.* Only an eighth of an inch has been removed by a second discharge.

*Repeated ten times or more.* Five repetitions of the discharges have lowered the seal less than an eighth of an inch, leaving a full seal of one and one-fourth inch. Five further repetitions produce no further visible effect on the seal. In our previous experiments we have repeated the test fifty times without apparent diminution of the seal.

*Snow.* We will now apply a test stronger than any we have tried this evening. It is a test severe enough, as we found in making the experiments for the City Board of Health, to siphon out a pot-trap eight inches in diameter.

We will retain the full length of our soil-pipe and stop up the opening above the roof with oakum. Then, by discharging both closets together, we shall produce a suction as great as any which could possibly be produced in practice as when the top of the soil-pipe is closed up by ice or snow.

The first discharge has left one and one-half inch of seal. At the end of five discharges there

is still one and one-eighth inch of seal left and five more produces no further apparent diminution of it. Thus we see the seal of this trap cannot be broken by any siphonic action we can try with ordinary apparatus used in plumbing.

*Self-cleansing Property of the "Sanitas" Trap.* It remains now to determine if the "Sanitas" trap is actually as self-scouring as it is claimed to be.

We have had a "Sanitas" basin and trap set above a waste-pipe of glass in order to examine the scouring action of the water discharged from a basin with a properly proportioned outlet both on the trap and the pipe below it.

*Discharge of the Basin.* We see that the water rushes through the trap and waste-pipe at a very rapid rate. The basin, when filled to the brim, holds about two and one-half gallons. It empties itself, when set with a waste-pipe having a good fall, in about three seconds. Hence, the water flows at the rate of nearly a gallon a second, and has an enormous scouring-force on all the branch piping connected with it.

We will now throw various substances into the bowl and trap and see whether they are retained in them or not.

We will first try a quantity of coarse coal ashes, and, to make the test somewhat severe, we will remove the strainer and throw into the trap pieces of coal with the ashes nearly an inch in diameter. Filling now the basin we find a single discharge has removed all the dirt and a second discharge has left the trap and waste-pipe as bright as ever.

I will now form a paste of softsoap and loam. The loam is a mixture of earth and clay. The combination of this and the soap forms in large quantity the kind of waste matter to which wash-basins are most accustomed.

All this matter is instantly carried through the trap and waste-pipe, and, after a second flushing, it does not leave a stain behind.

After trying a few other substances we will make a strong solution of soap and dirty water and let it dry on the pipe and then see if it will wash off after drying.

Large pieces of hair-felt, strings of jute, and tow, coarse gravel, pieces of stone an inch in diameter, nails, and matches are all whisked through the trap as easily as if they were nothing but house-flies. In short, every kind of substance likely to be met in usage, and a great many others, are carried through and away with speed and certainty, and the self-cleansing power of the trap is demonstrated.

We have found the soap dried on the glass tube is completely removed by the strong flushing from the basin. (This last test was tried on another occasion before the lecture.)

*Capillary Attraction.* The seal of a trap is sometimes slowly and silently drained off by bits of hair, sponge, or twine which get caught across the outlet of the trap, as shown in Fig. 20, and draws out its water by capillary attraction. Numerous experiments have been made of late on this insidious enemy to the life of water-traps, and it has been found that there is a limit to the height which these substances will carry the water above its normal level. We find this limit of height to be within three

inches for small quantities of long and fibrous substances such as might get lodged in traps. We must, therefore, form our trap in such a manner that the water will have to travel along the fibrous substance more than three inches before its seal

Fig. 20. Seal of S trap destroyed by capillary attraction.

Fig. 21. Seal of pot-trap destroyed by capillary attraction.

can be broken. The "Sanitas" trap has been so constructed (Figs. 22 and 23), and in no

Fig. 22. "Sanitas" trap resisting capillary attraction.

Fig. 23. "Sanitas" trap resisting capillary attraction.

case has it been possible to destroy its seal by the capillary attraction of substances which could be lodged in it in practice.

*Back Pressure.* Back pressure is a force now but little to be feared in plumbing. Before it became customary to ventilate our waste and soil pipes, pressure

Fig. 24. S trap emptied by back pressure.

in the sewers, either from winds or tides, or the heat of steam or chemical action, sometimes produced a serious back pressure in our house-pipes. Now we

no longer encounter the difficulty from these causes, since we are accustomed to have our pipes properly ventilated. It is only under certain rare conditions, such as when a trap is situated near the bottom of a tall stack of pipe and close to a sudden bend, that back pressure is produced by falling water compressing the air in advance of it. The bend in the soil-pipe prevents the escape of the air below as fast as it accumulates above under the falling water-plug.

To resist this pressure it is only necessary to have a sufficient body of water in the trap and to set the trap at a distance below the fixture it serves sufficient for this water to form in the pipe when subjected to back pressure, a column from twelve to sixteen inches long. (Fig. 25.) The weight of

Fig. 25. Deep seal S trap resisting back pressure.

such a column is ample to withstand any back pressure ever now encountered in good plumbing.

The "Sanitas" trap is made to contain a body of water heavy enough to easily resist any back pressure it can ever be called upon to bear in modern plumbing work.

**Evaporation.** When traps are not ventilated evaporation goes on with such slowness as to be scarcely perceptible. Nevertheless, it is best to have the trap contain as large a body of water as is consistent with its self-cleansing properties. An ordinary one and a half inch S trap holds about three eighths of a pint of water. A one and a quarter inch S trap holds less than one fourth of a pint. The "Sanitas" holds one and a half pints, or about as much as an ordinary three-inch pot-trap. This is sufficient to last, under ordinary conditions, over a year without renewal when the trap is unventilated.

Where the trap is ventilated, however, in the manner customary under our present plumbing laws, the seal of an ordinary machine-made S trap is licked up by the air-current in a very short time, varying in my own experiments from four to eleven days.

**Size and Material.** Traps for the smaller fixtures should be manufactured in one size, that is, of a capacity sufficient to fill the usual one and

a half or one and a quarter inch waste-pipe full-bore. In other words, the size of the traps should be governed by the size of branch waste-pipes. These pipes should never exceed one and a half inch in diameter, except for water-closets. Waste-pipes should not be less than one and a quarter inch in diameter. Hence, the capacity of the trap should not be less than this at any part, and to be self-scouring should not exceed this capacity at any part. The cleanout cups should be made of glass or of metal. Glass should be used for washbasins only, and then only when a possible fracture will not produce serious damage to frescoed ceilings below. With bathtubs, sinks, laundry-tubs, and all other fixtures metal cups should always be used, since even the best annealed glass is liable to be broken by sudden changes of temperature or by careless usage.

#### THE PREVENTION OF OPIUM ADDICTION, WITH SPECIAL REFERENCE TO THE VALUE OF GALVANISM FOR RELIEF OF NEURAL- GIC PAIN.<sup>1</sup>

BY J. E. MATTISON, M.D., OF BROOKLYN, N. Y.

PAIN is the paramount cause of addiction to opium. Barring slaves to the pipe—who are simply victims of a vicious indulgence—exceptions to this statement are so infrequent as to weigh little against its correctness as a whole. In an experience embracing many cases but a single instance to the contrary has been noted. Granting this, the great generic factor, and believing prevention better than cure, one can appreciate the surpassing importance of the therapeutics of pain in relation to the prophylaxis of this growing neurosis.

Peerless among anodynes is opium, yet it is potent for evil as well as good, and its power for ill is one of which we believe the profession at large has not an adequate conception, or, if aware of it, fails to realize it to the extent it deserves; and not until the mischief is done beyond their undoing do they rise to an appreciation of what a subtle enemy is often unbrushed behind a seeming friend.

The power of opium to make itself a necessity, to create a demand for continued taking, would be almost incredible were it not so often attested by sad experience. The writer's belief in this peculiar property becomes more profound with each case coming under his care, and when medical men in general accept it as a fact, and act accordingly, we believe the steadily growing proportions of this toxic disorder will be speedily checked and decline.

Pain, be the character what it may, if sufficiently persistent, and the giving of opiates too prolonged, will, almost unfailingly, beget this disease. But it is to the strictly neuralgic type, the one so often encountered by every-day medical men, that this assertion preeminently applies. It goes without saying that in no other land does this outcome of impaired nerve tone prevail as with us. Why this, is well enough known, and need not detain us here. The fact cannot be gainsaid that neuralgia abounds,

<sup>1</sup> Read before the Kings County Medical Society, February 17, 1885.

and that its treatment with opiates — especially morphia hypodermically — has made more opium habitués than can be placed to the credit of any other one cause.

It would illly become us to assert that this lamentable sequel can be entirely prevented, but we certainly think it can be largely lessened, and the special point of this paper is to invite renewed attention to a remedy the value of which the profession at large has not, we think, proper knowledge and appreciation, and which, in our opinion, outranks all others as a substitute for opium in the relief of neuralgic pain.

Dr. Anstie, in his unrivaled work on "Neuralgia," speaking of electricity in its treatment, said: "I shall make bold to say that nothing but the general ignorance of the facts can account for the extraordinary supineness of the mass of English practitioners with regard to this question." Nearly a decade and a half have passed since this was written, and yet we believe it is true, to-day, of many American medical men. Certain it is, no physician who has not had properly directed experience on this subject can form any idea of the possibilities for good possessed by a well-equipped galvanic battery. Anstie's estimate of it was: "The constant current is a remedy for neuralgia unapproached in power by any other save only blistering and hypodermic morphia, and even the latter is often surpassed by it in permanence of effect, while it is also applicable in not a few cases where blistering would be useless or worse."

With this opinion we are in full accord, and a growing experience serves only to strengthen our conviction of its truth.

In a paper by the writer<sup>2</sup> attention was called to the value of this agent in relieving migraine. Our present purpose is to ask consideration of its merit, by actual trial in the hands of those who have not employed it, for the relief of other neuralgic pain. Every physician who has given attention to the treatment of opium habitués well knows how often some form of neuralgia follows among the sequelæ of an opiate disusing. Those that slumber, as it were, during the opiate addiction often seemingly take on a new lease of life. Others that may be pronounced are, essentially, the outcome of impaired nerve tone due to the opium-taking. In either event they must be remedied, if we would have the prospect of permanent cure at all promising.

One danger ever menaces the ex-opium habitués — the occurrence of pain and the risk in again using opiates. To guard against this latter he must needs lend every effort, for on its success his future depends. He who has escaped the thralldom of opium is no longer like his fellows. The boon granted them, if required, is denied him, for one dose of the old narcotic may undo all done months or years before, a truth many a habitués learns by sorrowful experience, but one which, happily, proves at times an increased and assured protection against future ill.

To the ex-habitué some substitute for opium is, then, a *sine qua non*, and of all such with which we have had any experience not one equals the galvanic current. It is a most valued ally, and our estimate

of its worth increases as experience with it extends. Points in its favor as compared with remedies given by mouth, so far as regards unpleasant gastric or other results, need not be stated; they are self-suggestive. One great advantage it possesses is promptness of effect, often surpassing in this respect even hypodermic morphia. The latter is sometimes ineligible, and when it acts kindly as an anodyne is frequently followed by such nausea, vomiting, headache, or general discomfort as to make the freedom from pain a relief dearly bought. No such charge can be made against the current, for when it fails, as at times it will, disagreeable sequelæ are not noted, if the battery has been properly equipped and rightly managed.

We are not aware that ex-opium habitués possess any peculiarity or susceptibility that makes neuralgic pain in them any more amenable to galvanic treatment than when it occurs in those not addicted to this drug. If this be true, it follows that the latter are as eligible subjects for the constant current, with just as rich promise of successful result as the former. Authorities agree as to its value. Bartholow says: "There is no fact more certain than the power of galvanism to relieve pain." Others, commending it, declare, as did Anstie, that lack of knowledge as to its value and consequent failure to employ it are largely the cause of its limited use.

This paper, as asserted, is a plea for securing a practical acquaintance with it at the hands of those who are now unaware of its worth. Electricity need not and should not be limited to the specialist. Every practitioner, if he will, may avail himself of it. Careful study of its theory will pave the way for success in its practice. Varied works on this topic are at his service, and, without disparagement to others, it may be said that the last edition of De Watteville's treatise will bring him quite abreast the times regarding it.

One obstacle to its more general employment may have been the lack of a battery that combines three features desired: lightness, smallness, cheapness. Faradic batteries of this type abound, but the interrupted current is of very limited value in true neuralgic pain. Had the demand for such a battery, incident to a more extended use of the constant current, been created, we are inclined to think it would have been promptly supplied. At present we know of no galvanic battery, unless specially constructed, that contains less than ten or twelve cells. Absence of a smaller and less costly instrument has, we think, been a bar to more extensive use of electricity. As a fact, in very many cases, the larger batteries are not needed. Of all forms of neuralgia facial is the most frequent, and in many instances a current of from two to four cells will suffice for its relief. We have repeatedly proved this with the Bartlett battery, made by the Galvano-Faradic Company, which, when a large instrument — twelve to thirty-six cells — is desired, has many points in its favor.

For those desiring a smaller battery the Kidder Manufacturing Company make one of four cells, which we have known give entire relief in severe neuralgic pain. It is small, inexpensive, and efficient. Not only is it valuable in professional hands, but it is especially adapted to domestic use, details

<sup>2</sup> Louisville Medical News, February 23, 1884.

of its management being easily acquired and applied.

Galvanism is not here lauded as a specific for neuralgia, nor is it intended to serve as a substitute for well-directed general treatment to improve the impaired nerve status on which the painful bouts depend. Neither of these rôles will it fill, although cases have been recorded where entire and permanent freedom from suffering has followed a single application, but this is not the rule. The great point gained by it is relief from pain without resort to opium, the exceeding importance of which will be all the more appreciated when one considers the oft-recurring outbreaks so peculiar to this disorder and the consequent need of repeated narcotic doses to secure the desired result.

Having decided on a trial of galvanism, the strength of current, points of application, and length and frequency of sittings must be duly considered. Regarding all these careful study should be made of some standard work on the subject; but in general it may be said, as to the first, it must be painless, nothing more than moderate tingling, burning, or redness under the negative pole. When used about the head a current strong enough to cause slight flashings of light if the eyes are closed when the circuit is broken will usually relieve the pain. In a battery newly charged we have known two cells suffice. Minimum strength is required about the brain; marked flashes, vertigo, or faintness are excesses, and must be avoided.

Neuralgia of the trunk and extremities requires a stronger current, the extent of which individual peculiarity must determine.

The site of the electrodes varies according to the nature of the case, but, as a rule, the positive pole over the vertebra corresponding with the exit-point of the nerve affected and the negative over the painful part will succeed. Some insist on a reverse order,—that is, negative to the spine,—but in general it is not essential; either will answer, though, as a fact, we have invariably noted in bilateral cases earlier subsidence of pain under the negative pole. In the latter, exceptions to this method may be practised: for instance, in migraine an electrode on each mastoid, or in supra-orbital or temporal, over each eye or temple.

Length of sitting varies. Anstie asserts five to fifteen minutes the rule. We have repeatedly known less than the first sufficient, and have not hesitated to continue it more than the latter if the attack showed tendency to subside. Prolonged *séances* are more allowable to parts other than the head and face. Pelvic neuralgias and sciatica most often require extended sittings. If several painful points, the current can be no longer given by varying the site of application, taking care not to break it, by lifting the electrode, but allowing it to glide from one place to another.

Frequency of sitting depends on frequency of attack. Every bout should at once be arrested. The more promptly this is effected the better. It lessens nerve exhaustion and tendency to recur. Dr. Herbert Tibbets cites a striking case bearing on this point. A patient for two years had been subject to attacks of neuralgic pain, occurring from six to twenty times daily. She was galvanized

twenty times on the first day. Improvement was rapid; after a month's treatment attacks were reduced to one or two weekly. In three months patient was cured. Dr. Tibbets believes that in severe and obstinate cases the full sedative effect of the current is only to be obtained by applying it as frequently as the paroxysms of pain recur.

Two cases, under personal care, will illustrate. Mrs. A. became a habitué from using morphia for relief of pelvic pain. After twelve years' addiction, reaching a daily taking of twelve grains hypodermically, she came under the writer's care and recovered. During her convalescence she had repeated attacks of neuralgia—seventeen in all—and some exceptionally severe. Thirteen were ovarian, three trigeminal, and one intercostal. In every instance, the constant current gave entire relief after a *séance* ranging from six to twenty minutes, with a strength of six to sixteen cells. The negative pole was always applied to the painful part. This lady's husband is a physician, and in his hands the battery has since served her well.

Mrs. B., recovering from an opiate addiction, had from one to four neuralgic attacks daily, for nearly three weeks, and then at increasing intervals a fortnight longer. They were bilateral, supra-orbital, and through temples. Some were intense. Without exception, every one was entirely relieved in from three to seven minutes by a two to four galvanic current. The poles were applied to the painful points, and it was invariably noted that the pain first subsided under the negative pole. Patient was instructed how to use the battery, and repeatedly did so with success. Leaving our care she sailed for the Bahamas, and in order to be prepared for possible neuralgic returns, we supplied her with a four-cell Kidder galvanic, the efficacy of which we had determined by several trials, in which a two-cell current gave entire relief. Tidings received since her leaving prove it retains its power to remove the occasionally recurring pain.

Nothing could be more satisfactory—in fact we know of nothing so much so—as the prompt and complete success of galvanism in these cases. And they are not isolated examples. Their like abound in medical annals. The Germans, notably Niemeyer, have given some most striking cases, making them, as has been well asserted, “among the most interesting facts in therapeutics that have ever been recorded.”

Since, then, there is at command a remedy so effective and, withal, so free from unpleasant results, we urge the profession to avail themselves more largely of this powerful auxiliary in the therapeutics of neuralgic pain, instead of the so common resort to opiates, and especially the facile—yet so often fatal as regards the mental and physical health and happiness of many—hypodermic syringe. It is a trite story, but it is a true one—this using of opium to one's harm. Its importance cannot well be over-insisted on, and the right-minded physician must admit and appreciate it if he would conserve the well-being of many who consign themselves to his care.

But it is so easy to prescribe an opiate for neuralgic pain, that medical men—unmindful of possible harm—have been too often content to

follow the old routine. Is it not time to begin a new order of things, to get out of the old path into one that will lead to better results, since free from the former risk?

Would it not be wiser for every practitioner to equip and acquaint himself with galvanic battery, and make trial of this, rather than, at once, to opium? Would it not be far more prudent to provide his neuralgic patient—if occasion required—with this, and instruct as to its use, rather than supply morphia, or an opiate prescription, which, as every one knows, can be so easily refilled, to excess, or, most pernicious of all advice,—since it is almost sure to have a ruinous ending,—to counsel the purchase and self-using of a hypodermic syringe?

Let each one put this query to himself and weigh well the answer.

#### A CASE OF DERMOID OR PILIFEROUS TUMOR, WITH CURE BY SPONTANEOUS OPENING INTO THE INTESTINE.<sup>1</sup>

BY WALTER F. ATLEE, M.D., OF PHILADELPHIA.

M. C. came to me in May, 1884, on account of a lump she had that day discovered in the lower part of the belly. She was thirty-two years of age, of medium size, with the appearance of good health. Her menses always came regularly every four weeks, never were profuse, and, as a general rule, lasted but two days.

This lump appeared to be egg-shaped, the long diameter in the direction of the spinal column, in size perhaps six inches in its greatest length, and placed rather above the womb, and somewhat to the left of the median line. She complained of pain and of obstruction to the passage of the stool. For this condition the use of a pill composed of opium and of the compound extract of colocynth was advised. A few days afterward, on account of complaint of difficulty in passing the urine, a drink of bitartrate of potassa was recommended for use. In July, on account of troubles of digestion, bismuth and strychnine were prescribed, to be used before meals, and pills of carbonate of iron to be taken after. Early in September pills of ergotine were ordered, and their use was continued again in October and in November and December. During this time the lump appeared to be growing rather smaller, and it was certainly becoming softer. On the eleventh of November a considerable quantity of matter like thick gruel, white, and with no odor, came away from the bowel. This, under the microscope, was seen to be composed of the exfoliated epithelial cells and the secretion from sebaceous glands. This continued to come from time to time, and, as it did, the lump became smaller. On the tenth of January hair began to come, some of it long and very black, and the most of it of a light brown, and but four or five inches in length.<sup>2</sup> On the sixteenth of January the matters that came away were very small in quantity, greenish in color, and of a very bad odor. Since that time there has been nothing of notice in the discharges from the bowels, except twice a slight quantity of blood. There is now no sign of the tumor.

These dermoid or piliferous tumors are interesting, surgically, from the obscurity they throw over diagnosis, and in the complications they occasion. In the case just related the tumor was believed to be a uterine fibroid for several months; in fact, until it was observed to become quite soft, from hard, as it had always been before. In a pathological point of view their interest is very great indeed, and also in one of comparative physiology. By far the larger number of dermoid cysts—indeed, the immense majority of them—are ovarian; but no matter in what part of the body they may be found, or what may be the sex of the patient, the doctrine of “the continuous development of tissues out of one another,” as Virchow calls it, will suffice to account for the growth of all ordinary dermoid or piliferous tumors. Inherent in the tissues of the body is a peculiar formative and reproductive power, and it operates in the production of these strange tumors, as it does in the large number of multiform morbid growths which spring up everywhere under circumstances impossible for us to explain.

In ovarian morbid growths the kind of tumor that is formed depends upon the strength of the formative impulse. In ordinary cases the force of formative power goes no further than the production of cyst-walls with a secreting endothelium which pours out fluid contents. In some cases the cell growth is enormous, and yet there is no disposition to organization, and piliferous excrescences, cancerous and colloid masses, show themselves. In others again, imperfect attempts at organization are seen, as in those called dermoid or piliferous, on account of what is most usually found in them.

The origin of all these cysts is traced, indirectly by way of exclusion, and directly by way of observation, to the development of the ovisacs or Graafian vesicles; and, when we consider what these ovisacs are, we need never be surprised at the contents of these cysts, and at the abundance, the nature, and the variety of these contents. When skin, hair, teeth, and so on, are met with it is quite in accordance with known facts in comparative physiology to look upon tumors containing them as imperfect attempts at organization arising from the powerful germinative aptitude of the ovary. The formation of imperfect tissues is reached without ever going so far as the formation of an organ, let alone that of an organism. Such formations may be looked upon as examples of parthenogenesis, as imperfect vestiges in the higher animals of a regular physiological act in some of the lower ones.

#### REPORT ON DERMATOLOGY.

BY G. H. TRAP, M.D.

##### GASTRO-ENTERITIS FAVOSA.

At a meeting of the Imperial Society of Physicians in Vienna, Professor Kundrat showed pathological specimens taken from an individual who had suffered from severe and extensive favus, not only of the scalp, but of the whole cutaneous surface, the development of the disease having been so excessive that the patient at one time had been exhibited by Professor Kaposi. The patient soon

<sup>1</sup> Read before the College of Physicians of Philadelphia, March 4, 1885.

<sup>2</sup> A considerable quantity of this hair was shown to the College.

<sup>3</sup> Wiener Med. Zeitung, No. 42, 1884.

afterward developed phlegmonous inflammation in the right popliteal space and died therefrom. The revelations of the autopsy were extraordinary. Besides fatty infiltration and degeneration of various organs, due to chronic alcoholism, and extended hypostatic pneumonia, a peculiar state of things was found to exist in the entire alimentary canal. Upon the gastric mucous membrane, which was somewhat swollen and mammillated, were to be seen a large number of small erosions, and also many yellow spots situated in the epithelium and upper layers of the mucous membrane. There were also losses of substance as large as hempseeds, covered with yellowish-brown exudation, and at the pyloric orifice of the stomach extensive infiltration of the mucous membrane, which was covered with croupous exudation. In the small intestine, besides the appearances of catarrh, there existed here and there small gangrenous spots, while in the large intestine ulcerations as large as a cent were to be seen, situated singly and in groups, the lowest layers of the mucous membrane and the submucosa itself being either exposed or covered with necrotic tissue. The picture presented by the stomach was so unusual that the idea of a parasitic disease, favus affecting the mucous membrane of that organ, suggested itself and the use of the microscope confirmed the correctness of this supposition, the yellow spots being composed of masses of the *Achorion Schonleinii*, while the same vegetable organism was found to exist in abundance in the croupous exudation which covered the gastric mucous membrane. In neither the small nor large intestine, however, could the presence of the fungus be established. This condition of things is interesting, being unique, inasmuch as one of the mould fungi was found to be the cause of extensive pathological changes in the stomach and intestines. Although in dilatation of the stomach or in necrosed portions of that organ mould fungi are often found, their presence in such cases is accidental and of no aetiological significance in connection with any pathological process which may be present. In the present instance, however, there existed in the stomach severe inflammatory processes of a croupous nature, and wherever these processes were situated, the organisms peculiar to favus were to be detected. In the intestines, although none of these organisms could be found, the picture presented was so unusual, the distribution of the ulceration only between the folds of mucous membrane represented so little the ordinary appearances of enteric diphtheritic processes, that Kundrat was inclined to regard the whole pathological process as gastro-enteritis favosa.

#### CUTANEOUS REGIONS OF SPECIAL SENSATION.

During the past year three observers have investigated this subject independently of each other, and with remarkably concurrent results. Blix<sup>2</sup> takes as starting-point Müller's law of the specific energy of nerves, that any irritation of a sensory nerve arouses one and the same sensation, whatever be the nature of the irritation. If this is true it follows that functional activity of any peripheral sensory apparatus produces always the same effect: that of exciting the nerve fibres to which it belongs. The

kind of sensation which is thus aroused is dependent upon which nerve fibre conveys the irritation to the central nervous system, while the peculiar function of any given terminal sensory apparatus is, so to speak, selective, being capable of receiving only the one form of impression to which it is adapted.

As is well known, there are methods of irritation which influence the nerve fibres themselves and which, therefore, in case there exists a specific energy of nerves, should be capable of exciting different sensations according as they affect different nerve fibres leading to central nervous apparatus possessed of diverse functional activity. If it were possible to apply such irritation so as to affect only a single primitive nerve fibre, the irritation should arouse the special form of sensation which is peculiar to the central apparatus of the irritated nerve, irrespective of the method of irritation employed.

That the skin is the seat of several kinds of terminal nerve apparatus is apparent, not only from its anatomical structure, but also from the many varieties of sensation which are perceived upon appropriate cutaneous irritation. These sensations are usually divided into three classes: sensations of pressure, of differences of temperature, and of pain. The question now arises as to whether the specific nerve structures in the skin are the same or different for different sensations, that is, whether the same terminal sensory apparatus is capable of transmitting different sensations. If the terminal nerve structures in the skin are different for different sensations, they must occupy different regions of the skin, and however near to each other they may be situated, it should be possible to excite isolated activity in only one of these organs or its attendant nerve fibre.

Inspired by such reflections, Blix adopted local faradisation of the skin as a means of irritation. One pole of an induction coil was attached to a flat, moist conductor of large size so as to be in contact with an extensive surface of skin, the other pole being in connection with a small metallic point. By this arrangement the current of electricity, provided it is not too strong, is perceived only at the point of contact with the skin of the metal point. The use of a sufficiently strong current causes merely a generalized sensation of pain, while a milder current causes pain only in regions of the skin where the epidermis is thin, but not where the epidermis is thick. For purposes of experiment the most suitable strength of the electric current was found to be that which excited no feeling of pain when the pointed electrode was merely in contact with the skin, but only caused such sensations when the instrument was pressed firmly against the skin. In this way, by gradual increase of pressure, a gradually increasing irritation of the cutaneous nerves may be brought about. Contact of the electrode with the skin causes at first merely the sensation of pressure, provided the current is of the proper strength. By gentle increase of the pressure exerted, this sensation gradually changes to the characteristic feeling of pain caused by the application of the faradic current to the skin. Occasionally, however, the point of the electrode, while being moved about in contact with the skin, strikes a region where by gradual increase of pressure a well-defined sensation of heat or cold, most commonly cold, is

aroused. By still further increase of pressure, this feeling of warmth or cold is transformed into the ordinary impression of pain, which assumes in different, although contiguous, regions of the skin different character. Usually it consists of a sensation of burning or pricking, sometimes being, here and there, more dull and vibrating in quality. Electrical irritation, therefore, causes different sensations in different regions of the skin. In one place it excites only pain; in another the feeling of cold; in a third the sensation of warmth; and in a fourth the sensation of pressure; from which it follows that the kind of sensation is not dependent upon the nature of the irritation to which it is due, but upon the specific energy of the nerve structure which happens to be affected. The cutaneous regions which offer the most favorable conditions for promptly detecting these points of different sensation are the backs of the fingers and hands.

Similar results are obtained by using merely a metal point without electricity. If a rounded point of cool iron or steel is slowly moved over the back of the hand, in contact with the skin, it arouses the sensation of cold only at certain points, while between these points are larger or smaller areas of skin where no such sensation is felt. Only when the instrument arrives in the neighborhood of a region which is sensitive to cold is there perceived a slight feeling of cold, which increases in intensity as the metal point approaches the sensitive spot. Of course, the nearer such spots of cold perception are to each other and the thinner the epidermis, the finer must be the metallic point which serves to differentiate them. In regions of the body where they are more discrete and where the epidermis is thick, it is necessary to use a more blunt and colder instrument in order to detect them. By the application to the skin of a metal point which could be kept at any desired degree of heat, the author discovered that there also exist in the skin certain spots which are affected only by the application of heat, and that these spots are separate from, and do not coincide with, those at which the sensation of cold is perceived. As a rule the cold points are more numerous than the warm points and both kinds are most thickly grouped upon the backs of the hands and fingers, less so upon the face, while upon the arms they are less numerous and upon the legs are quite sparsely situated. Upon the legs, for instance, there are cutaneous regions, of several square centimeters in extent, which are non-sensitive to both heat and cold. These points of special sensation are irregularly distributed and without definite arrangement, save that on the backs of the hands and fingers they are more thickly grouped than elsewhere. The thicker the epidermis the more difficult is their detection; but even on the palmar surface of the hands and fingers it is possible to demonstrate their separate and individual existence.

Goldscheider<sup>3</sup> has arrived at practically the same conclusions as Blix, but is of the opinion that these cutaneous regions of special sensation have a more or less definite arrangement, the prin-

ciple of which is as follows: They are disposed in straight or slightly curved lines which radiate from certain points in the skin. By reason of the fact that the lines radiating from different points cross each other, there ensue inclosed areas of skin in which no points of special sensation exist. The central points, from which radiate the spots sensitive to differences of temperature, also serve as radiating centres for the spots sensitive to pressure, and as a general rule these central radiating points are situated directly over the hair papillae, but even in hairy regions of the body there are also to be detected central points of radiation which bear no such relation.

Donaldson, of Johns Hopkins University,<sup>5</sup> using thermal stimuli, has found that the distribution of sensitive spots in corresponding parts of the body differs in different individuals; that in the same individual the disposition in symmetrical regions of the skin is different; that the number of points sensitive to cold is greater than that of the points sensitive to heat; that the relative abundance of the two kinds varies in different parts of the skin; and that in a general way there are two grades of each kind of sensitive points, that is, those which react almost always and those which react less than half the time, and in which the sensation is comparatively faint. He finds that the spots are very small, as a rule less than a millimeter in diameter; that their power of perception is easily exhausted, and that the sensation called forth by a single stimulus often lasts for some minutes after the removal of the stimulus. That these points of special sensation are situated in the skin and not beneath it is shown by the fact that they move with the skin. To determine whether any definite histological peculiarity could be detected in the anatomical structure of these spots, two such regions of skin, one sensitive to heat and the other to cold, were excised and subjected to microscopical examination. No special structure, however, could be found which might have any association with the special sensitiveness of the spots, while experiment further demonstrated the fact that cicatrices are also possessed of regions of special sensation.

Eulenborg<sup>6</sup> has been investigating cutaneous sensibility as to differences of temperature, with an instrument composed of two thermometers, adjusted after the manner of the two points of an aesthesiometer, and so arranged that one thermometer could be heated to any desired degree. He finds that he is in a position to confirm the conclusions of Goldscheider, so far as they concern cutaneous sensibility to heat and cold, in almost every essential particular.<sup>7</sup>

#### ETIOLOGY OF LUPUS VULGARIS.<sup>7</sup>

This subject was under discussion in the Dermatological Section of the Medical Congress at Copenhagen, during last summer. The opinion of every one who took part in the debate, except Kaposi, was in favor of the view that lupus vulgaris is tuberculosis of the skin, the undoubted presence in the nodules of lupus of a bacillus in every way

<sup>3</sup> Monatshefte für prakt. Derm., Nos. 7, 8, and 9, 1884, and Vierteljahrschrift für Derm. und Syph., 3 and 4 Heft, 1884.

corresponding to the bacillus of tuberculosis, its cultivation in media outside of the body, and the production of tuberculosis in animals by inoculation with such cultivation, being the reasons for this opinion. Kaposi vigorously opposed this idea, relying chiefly upon the manifest difference in the clinical course and appearance of lupus and of tuberculous ulcers of the skin, and expressing his conviction that such diverse phenomena could not result from the same cause. In answer to this it was suggested that it is not an impossible or unusual thing for the same pathological process to give rise to different manifestations, a common example of which is syphilis, the polymorphic nature of its cutaneous lesions being one of their most characteristic features. The consensus of those present was that although "all tuberculosis of the skin is not lupus, yet lupus is always cutaneous tuberculosis."

Evidence is accumulating which goes to show that tuberculosis and scrofula are closely allied processes, and lupus thus takes its place among the scrofuloderma hitherto generally assigned to it by the French school of dermatology, but with a vagueness of mental grasp necessitated by ignorance of the nature of scrofula: "Ce panier dans lequel on jette, indistinctement, toutes les maladies, qui frappent les enfants de moins de quatorze ans, et dont on ne connaît pas la cause." There are three cases mentioned in a footnote in the number of the French *Annals of Dermatology* for October, 1881, which are interesting in this connection. The feature common to these cases was the development of the typical lesions of lupus vulgaris in portions of the skin which had for a long period of time been in continual contact with the purulent discharge, in one instance from a presumably tuberculous fistula in ano, and in the other two from tuberculous disease of bone. These observations were made before the existence of such a thing as the bacillus of tuberculosis was thought of, and are therefore of suggestive rather than evincive value.

## Reports of Societies.

### SUFFOLK DISTRICT MEDICAL SOCIETY.

SECTION FOR CLINICAL MEDICINE, PATHOLOGY, AND HYGIENE. SPECIAL MEETING.

ALBERT N. BLODGETT, M.D., SECRETARY.

FEBRUARY 16, 1885. By courtesy of Gen. F. A. Walker and the Boston Society of Arts, the Clinical Section met in the hall of the Massachusetts Institute of Technology.

The chairman not being present, Dr. J. W. ELIOT was chosen chairman *pro tem*.

The paper for the evening was by J. PICKERING PUTNAM, Esq., upon

#### THE PRINCIPLES OF SANITARY PLUMBING.

The paper was illustrated by drawings and by elaborate fixtures with water-supply, by which practical demonstrations were introduced showing the behavior of various forms of traps under the conditions of actual use. The efficacy of sewer

ventilation was also alluded to, and the action of the air in ventilating shafts connected with the sewer-pipe was demonstrated by means of a long coil of iron pipe at variable points within the sewer-main. The flushing of the system of pipes was effected by a deluge of water liberated by the simultaneous discharge of two closets of enormous water capacity. In no case was there a tight seal during the experiments, but the air always traversed the trap in the direction of the flush. The point most earnestly advocated by the speaker was that traps of such a construction should be employed in house drainage as should allow the passage of air through them and still not be exhausted of water, and thus offer an obstacle to the passage of the emanations of the drain into the air of the dwelling.

MR. E. S. PHILBRICK, civil engineer, remarked that the closets exhibited in the experiments differ from those in common use. These closets are minimally regulated so as to receive but two thirds of the full capacity of the closet as a flushing charge. This does not allow so large a quantity in any closet as was employed in the experiments. In practice the water is not running when the closets are discharged, as is the case in the experiments.

So far as the risk of siphoning is concerned, the trap shown seems to be a safe and proper substitute for trap ventilation, and is a means for avoiding such ventilation. It does not, however, follow that ventilation is superfluous. The ordinary S trap does not easily lose its seal. Even when two plunger-closets of the large size shown in the demonstration are simultaneously discharged, a thing which surely must occur very rarely only, if ever, in actual practice, it requires several such sudden plunges of this unusual amount of water to break the seal in the trap.

Furthermore, the closet used for the experiments is an antiquated style, which has been abandoned for more practical and economical forms of closet, and is not now made and cannot be bought. The outflow is too large and the amount of water used far too great. The discharge in these closets is from thirty to forty per cent. quicker than in the improved forms of closet.

The pressure is also much greater here than in closets in practical use in dwellings. The destruction of the seal in domestic traps from siphoning due to the gush of water from closets must be practically a rare occurrence.

Another faulty point in the experiments is the fact that air is allowed to enter the drain only at one point, namely, the single place at which the S trap is inserted, and a most unusual suction force is thus brought to bear at one isolated spot. In practice there are numerous traps in domestic service, and the suction is not exerted solely at one selected point, as is the case in this demonstration. In point of fact domestic traps do not siphon out in practical usage when guarded by ventilating pipes.

The pattern of closet shown, the Jennings model, is not cleanly, and is now replaced in use by other simpler and more desirable forms.

The free access of air to every branch of the soil-pipe is important, not only as a means of assisting the escape of gases from the interior of the pipe,

but also as a means of facilitating the passage of water through its lower parts. The flow of water through a closed system of drain-pipes may be compared to the escape of a liquid from a bottle. In order to obtain a free discharge it is necessary that some provision be made for the entrance of air at the upper end of every branch. The accumulations of gas in lateral branches of sewers are not influenced by ventilation of the main shaft. Lateral drains, therefore, should be ventilated independently of the main shaft, so as to allow air to traverse their entire length. The general system of soil-pipe ventilation as now enforced is not the most desirable or efficacious. The laws enacted by the city government in relation to plumbing are oppressive, and the plan which is enforced in regard to sewer ventilation is not perfect.

MR. E. W. BOWDITCH, sanitary engineer, stated that the lateral drains in house sanitation should be ventilated if for no other purpose than to prevent corrosion of the interior of the pipes from the action of the gases formed in or accumulating in the branches of house-drains. Sewer gas attacks lead pipe more than air does, and the parts which are corroded are always those which are dry, and thus exposed to the action of the gaseous contents of the pipes. Soil-pipes which were put in years ago and were not ventilated are always found corroded on removal. The old form of trap is also often found corroded, sometimes presenting numerous perforations through the entire thickness of the trap; and this, when observed, is always above the water-line of the trap. This is not confined to water-closet traps, but affects the traps of all kinds of domestic fixtures. No amount of flushing will keep the interior of drain-pipes clean so that noxious gases and probably also vegetable fungous growths will not be found in them. The provision for a freely circulating current of air is necessary to prevent these two sources of contamination. The soil-pipe exhibited seems to be excellent, and an improvement on that now in use. It would seem that this might be lined with porcelain, a thing much to be desired. It will certainly allow repairs and renovations much more easily and economically than any form of soil-pipe now in use.

MR. TUTT, a plumber, thought the trap shown would be likely to clog with the greasy matters from a kitchen sink.

MR. PUTNAM stated that the trap had never been tried in the drain from a kitchen sink.

MR. BOWDITCH thought the improved joint for drain-pipes would make it possible to construct a better quality of pipe. Some of the pipe now manufactured is cast so unevenly that it will not sustain a column of water of its own height. The strain on the pipe from variations in temperature would also be greatly diminished by the improved joint.

An opportunity was offered, at the close of the discussion, for a thorough examination of the apparatus by the audience, after which the meeting adjourned at 10.15 o'clock.

—Dr. Holmes makes a suggestion in *The New Portfolio* to the effect that while a doctor's patients must put their tongues out, a doctor's wife must keep her tongue in.

## NEW YORK COUNTY MEDICAL ASSOCIATION.

STATED meeting, April 20, 1885.

### INCONTINENCE OF URINE IN CHILDREN.

DR. J. LEWIS SMITH read a paper on this subject, the first portion of which was devoted to a consideration of the anatomy and physiology of the bladder, especially as regards its muscular coat and nerve-supply. The enuresis, which was more common among males than females, might be both diurnal and nocturnal, but was more frequently nocturnal. He mentioned eight causes, two of which might sometimes be present in the same case.

(1) Too great acidity of the urine, causing undue contraction of the bladder.

(2) Increased quantity of urine.

(3) The presence of stone in the bladder, in which case the incontinence is both diurnal and nocturnal.

(4) Abnormal contractile power of the muscular coat of the bladder. The importance of this cause is shown by the fact that belladonna, which controls muscular irritability, is useful in such a large number of cases of enuresis.

(5) Weakness of the muscular fibres constituting the sphincter of the bladder. This is rare in children in good health, and Dr. Smith gave an account of one case in which it was associated with spina bifida.

(6) Reflex action through the agency of the nerves supplying other organs in addition to the bladder. In this class are the cases due to structural disease of the spine, ascariasis in the rectum, phimosis, preputial adhesions, etc.

(7) The dreaming of the child that it is in a convenient place for urinating. To this psychical cause attention has been directed by Dr. Roberts Bartholow. That the enuresis is to a considerable extent under the control of the will is shown in cases where the habit has been broken up by the sending of the child among strangers or to boarding-school, where the sense of shame has constituted an influence sufficient for the purpose. Numerous instances are also on record where a flogging has permanently broken up the habit.

(8) Malformation of the bladder or its appendages. Dr. Madden has reported the case of a young lady who suffered from a constant dribbling of urine, both by day and night, in which he found, on examination, that there was a malformation of the right ureter, which discharged the urine from the kidney on that side directly into the vulva instead of into the bladder.

The prognosis, Dr. Smith said, naturally depended on the cause or causes of the trouble. When the affection was not controlled before, the influence of puberty or of marriage and pregnancy seemed to be well founded; but, of course, treatment was not to be delayed with any such idea in view. In the treatment the great point was to discover the cause. If the affection seemed to depend on the character of the urine, this was to be rendered as bland and unirritating as possible, and Dr. Smith said that since he had recognized the acid character of the urine as a frequent cause of incontinence he had been able to treat very satisfactorily quite a large

class of cases which had formerly proved troublesome. It was his practice to endeavor to render the urine as bland as tepid water. If there was acidity he gave from three to five drops of liquor potassæ, well diluted, three, four, five, or six times a day, until the urine became neutral in reaction, and then to continue the alkali in just sufficient quantities to maintain the neutral condition.

When there was increased functional activity the great reliance was to be placed on belladonna. The tincture was the preparation commonly used in this country, and of this five drops might be given every night and morning, the dose being increased by one drop each day until the desired effect was obtained or the physiological action of the drug had become apparent. When belladonna was found efficient it was to be kept up for some weeks in full doses, and the quantity then gradually diminished. This agent had been highly lauded by Trousseau, who used it in large doses. Dr. Smith related a case in his own practice in which a girl eleven years old, who suffered from both diurnal and nocturnal enuresis, and who had previously taken belladonna and other remedies, was cured. The urine was highly acid, and the treatment which he prescribed was five drops of liquor potassæ three times a day (or more, if this was necessary to keep the urine neutral in reaction), and tincture of belladonna in nine-drop doses, the quantity gradually to be increased to fourteen or fifteen drops.

If the enuresis were due simply to the large quantity of urine secreted, the liquid food was to be restricted, especially toward evening, and if diabetes were present, of course the treatment appropriate to that disease was to be adopted. In diabetes insipidus ergot was found to be of great service. Suspicion of the presence of a stone in the bladder would be excited by painful micturition, increased quantity of mucus in the urine, and the sudden stoppage of the full stream. The use of the sound would confirm the diagnosis, and the stone could then readily be crushed. In every case of incontinence it was important to make a careful examination of the parts contiguous to the bladder, such as the rectum and the genital organs, for the existence of ascarides, phimosis, preputial adhesions, hardened smegma, etc. If the enuresis were due to paresis of the sphincter, a treatment very different from that of belladonna was required, and here ergot, either alone or combined with nux vomica or strychnia, was found very useful in restoring the impaired innervation and stimulating muscular contractility. Two years ago Dr. George B. Fowler, of New York, had reported two very interesting cases, in which there was fecal incontinence also, treated with ergot in combination with strychnia. In one there was a relapse, which was successfully treated with ergot alone, given by the rectum. Here there was a markedly relaxed condition of the sphincter ani, indicating, no doubt, that there was also relaxation of the sphincter vesicæ.

A considerable number of remedies which had been formerly employed to a large extent for incontinence of urine were now seldom used; but some of them were still deserving of confidence in certain special cases. Among these was strychnia. In children under four years of age there was some

danger in giving it, and it was better to employ nux vomica under the circumstances, but above that age it was perfectly safe to use it. Tincture of cantharides, although as a rule an unpleasant remedy, could sometimes be employed with advantage if given in small doses. Cubebs and vegetable tonics and astringents were also sometimes called for. Dr. Smith then related a case reported by Eustace Smith, in which he successfully employed drachm doses of tincture of belladonna in combination with bromide of potassium and infusion of digitalis. It was to be borne in mind, however, that the English tincture of belladonna was only half the strength of the American preparation. Local treatment was often attended with a satisfactory degree of success, and the best agent for the purpose was nitrate of silver, applied for the cauterization of the neck of the bladder. Having referred to the use of baths and douches, Dr. Smith closed by speaking of the suggestion of Trousseau, that the patient should be required to urinate as frequently as possible during the daytime.

#### DISCUSSION.

DR. WILLIAM DETMOLD thought that in the majority of instances nocturnal enuresis was simply a vicious habit, but one which was very difficult to get rid of. He did not believe it was advisable to use the term incontinence of urine in this connection. The condition was one of enuresis, and not properly incontinence, true incontinence being indicated by a constant dribbling of the urine, both by day and night. This was observed in patients where there was some organic defect, as in the case of Dr. Madden, referred to by Dr. Smith, where the right ureter discharged into the vulva. When medicine had an effect in nocturnal enuresis he thought it was simply a moral effect, produced by the fear of the doctor or the consciousness of the dose. The more unpleasant the remedy, therefore, the more efficacious it was likely to be.

DR. J. W. S. GOULEY said that he thought Dr. Smith's anatomy and physiology needed a little revision. There was no sphincter vesicæ in the same sense anatomically as physiologically, the so-called sphincter vesicæ not being at all comparable to the sphincter ani. Forty years ago it had been demonstrated beyond question that there was no such thing as an anatomical sphincter to the bladder, though there was a distinct physiological one. It was not the circular muscular fibres, but the longitudinal and oblique ones, which exerted this sphincter-like action. In regard to the compressors urethre having any power to control the stream after it had once emerged from the bladder, as maintained by Dr. Smith, this was undoubtedly a mistaken idea, the physiological sphincter alone having any such control. He agreed fully with Dr. Detmold that the word incontinence, when applied to children who wet their beds, was incorrect, nocturnal enuresis being the proper term for this condition. The urine was passed, not because the bladder could not contain it, but because it had to hold too much. Dr. Smith had attributed to Professor Bartholow something which did not belong to him, as it was Jean Louis Petit, who lived more than a hundred and fifty years ago, who first called atten-

tion to the cause of nocturnal enuresis mentioned in connection with Dr. Bartholow's name. Petit stated that there were three classes of children who wet the bed: (1) those who were too lazy to rise and urinate; (2) those who slept so soundly that the sensation of desire which precedes the act of micturition was not sufficiently strong to awaken them; and (3) those who dreamed that they were urinating. Trousseau had added a fourth class, namely, those who through fear would not arise to urinate; but this class of Trousseau's, as well as the first class mentioned by Petit, he thought ought to be excluded, so that there would remain simply the second and third classes just stated. The most frequent causes of the enuresis were lithuria and polyuria, the latter being often met with in nervous children. Children, after they had become two or three years old, did not wet their clothing in the daytime, but only at night. In some instances such children retained the habit until they were grown, and he had seen men twenty-five, thirty, and forty years of age who were still subject to it. No amount of whipping could cure a child of wetting the bed; on the contrary, corporal punishment could do harm, and only make the condition worse. Lithuria was much more common in young subjects than was generally supposed. When this was present there was not an accumulation of urine, but a constant enuresis, both diurnal as well as nocturnal. Dr. Gonley said he did not at all agree with Dr. Detmold that treatment was of no service. On the contrary, he believed that there should be both local and general treatment. He thought, however, that it was a mistake to attempt to make the urine as "bland as tepid water," as Dr. Smith spoke of doing. This would only increase the enuresis, as very bland urine, like pure water itself, was known to be irritating to the bladder. Dr. Smith had spoken approvingly of lithotrity in cases of stone, but in children under the age of ten this operation had been tried and found wanting, lithotomy being in reality much more safe. As to cauterization, he trusted that Dr. Smith did not mean that this should be done with Lallemand's *porte-caustique*, as he regarded this as excessively dangerous. But in connection with the internal administration of iron, more particularly the old-fashioned tincture of muriate of iron, he had often afforded great relief by the introduction of the sound or catheter every two or three days. As a rule the steel sound, if skillfully used, was preferable to the gum catheter. In both girls and boys (although the number of the former that he had seen suffering from enuresis was quite small) he had observed excellent results from this practice, and he did not think Dr. Smith had mentioned the simple passing of the sound.

The Secretary, Dr. P. BRYNBERG PORTER, said that he merely wished to call attention to the much greater tolerance of belladonna, proportionally, in children than in adults. In the *British Medical Journal* of February 7, 1885, Dr. E. Paget Thurston had reported a case of nocturnal enuresis in a girl seven years old. At first she was given ten minims of tincture of belladonna three times a day, but this had no appreciable effect upon the condition. He then ordered the belladonna in drachm doses,

one dose to be taken in the afternoon, and another four hours later, just before going to bed. The second night there was no enuresis, after which only one dose a day was taken, at bedtime, and this was continued for four more nights. The cure was then complete and permanent. He had himself also often noticed in giving belladonna what large doses children could bear without showing the constitutional effects of the drug. He would like to ask Dr. Smith whether he had had any experience with chloral hydrate in nocturnal enuresis. During the last few years this agent had been highly lauded in this condition, and he had personally tried it in a number of cases where the affection did not seem to be dependent on any removable local cause. While, however, in certain instances it had seemed to afford partial relief, as a rule he had been disappointed in regard to its action.

Dr. E. G. JANEWAY made some remarks in which he said that from his own experience he could abundantly confirm the truth of Dr. Porter's assertion in regard to the very marked tolerance of belladonna in children.

Drs. C. S. Wood, F. V. White, and T. R. Varick, of Jersey City, also participated in the discussion, which was brought to a close by Dr. Smith.

Dr. SMITH said that in his account of the anatomy and physiology of the bladder he had derived his information from some of the highest authorities, and that for the statement in regard to the action of the compressor urethrae Bellield was responsible. In regard to the rendering of the urine bland and neutral in reaction, the good results which he had obtained since he had adopted this practice were sufficient, he thought, to justify him in continuing its use. He fully agreed with the gentlemen who had spoken in reference to the greater tolerance of belladonna in children, as was also the case with arsenic. In regard to chloral, he said that he had not tried it in this connection, but it seemed to him that if it was given in nocturnal enuresis it would only tend to aggravate the trouble by inducing more profound sleep. He agreed with Dr. Varick that it was very important that a careful study of the probable cause should be made in every case presented for treatment, and on this point he said he could not speak too strongly.

#### TRANSACTIONS OF THE CHICAGO GYNÆCOLOGICAL SOCIETY.

REPORTED BY W. W. JAGGARD, M.D., SECRETARY.

REGULAR meeting at Palmer House, Friday evening, March 20, 1885. The President, Dr. H. P. MERRIMAN, in the chair.

1. Dr. J. SYDNEY KNOX read a paper entitled "The influence of *Cnicifraga Racemosa* upon parturition."

After a *résumé* of the medical history of the drug, Dr. Knox gave the results of his clinical observations in one hundred and sixty cases of labor, — fifty-seven primipare, ninety-three multipare, — in which black cohosh had been exhibited. The average duration of the first and second stages of labor, in normal cases, in primipare, was seventeen and three hours respectively. Under the influence of black

coshoh the duration of the first and second stages of labor, in the fifty-seven cases observed, was six and one-quarter, and one and three-quarters hours, respectively. The average duration of the first and second stages in normal cases in multiparæ was twelve and one hours respectively. Under the influence of black cohosh, in the ninety-three cases observed, the average duration of the first and second stages was three hours and twenty-seven minutes respectively.

From these clinical observations Dr. Knox drew the following conclusions:—

(1) Cimicifuga has a positive sedative effect upon the parturient woman, quieting reflex irritability. Nausea, pruritus, and insomnia, so common in the last six weeks of pregnancy, are always rendered less distressing and often disappear under its administration.

(2) Cimicifuga has a positive anti-spasmodic effect upon the parturient woman. The neuralgic cramps and irregular pains of the first stage of labor are ameliorated and often abolished altogether. In fact, during the first indiscriminate use of the drug in all cases I had the mortification, with a few women, of terminating the labor so precipitately and without prodromic symptoms as to be unable to reach the bedside before the birth.

(3) Cimicifuga relaxes uterine muscular fibre and the soft parts of the parturient canal by controlling muscular irritability, thus facilitating labor and diminishing risks of laceration.

(4) Cimicifuga increases the energy and rhythm of the pains in the second stage of labor.

(5) It is my belief that cimicifuga, like ergot, maintains a better contraction of the uterus after delivery.

It is my habit, however, to administer fifteen to thirty minims of the fluid extract of ergot after the birth of the fetal head, and I have had but few opportunities of testing this effect of the cohosh.

My method of administration has been to give fifteen minims of the fluid extract of cimicifuga in compound syrup of sarsaparilla each night for four weeks before the expected confinement.

One fluidounce of the fluid extract of cimicifuga to three fluidounces of compound syrup of sarsaparilla—dose, one teaspoonful—makes just the required quantity.

#### DISCUSSION.

Dr. PHILIP ADOLPHUS had employed the cohosh, in the manner indicated by Dr. Knox, in one case with negative results.

Dr. EDWARD WARREN SAWYER thought the results obtained by Dr. Knox were astonishing. He thought there could be no doubt but that the drug had the physiological action to which allusion has been made. He would, at once, act upon the suggestion in his private practice.

Dr. W. W. JAGGARD thought that if the influence upon parturition, so clearly sketched by Dr. Knox, was capable of demonstration, he could agree with Dr. Sawyer's panegyric. Dr. Knox's carefully prepared paper was worthy of study and investigation. Dr. H. Webster Jones, formerly a prominent obstetrician in Chicago, had advanced similar views with reference to the physiological action of black cohosh,

in a paper published in the *Transactions of the Illinois State Medical Society* a few years since. Dr. Jones's advocacy of the drug as an oxytocic was well known to every practitioner in the city.

Dr. Jaggard desired to call the attention of the Fellows to the following subjects in Dr. Knox's paper:—

(1) Dr. Knox had stated that the average duration of the first stage of labor in primiparæ and multiparæ was respectively seventeen and twelve hours. Under the influence of black cohosh, the duration of this stage was abbreviated to six and one-quarter, and three hours, respectively. It was a matter of extreme difficulty to define the limits of the duration of the first stage of labor with such mathematical accuracy. The "personal equation" assumes great importance as a possible source of error. The subjective signs and physical explorations are not always sufficient to justify the diagnosis of the commencement of labor. Thus Dr. Lumpe<sup>1</sup> concludes, from the observation of several hundred primiparæ, that the cervical canal begins to dilate from eight to fourteen days before the expulsion of the child. Other observers assign a period of much briefer duration than the typical seventeen hours of Spiegelberg, to which Dr. Knox alluded.

Apart from the difficulty in the determination of the commencement of the first stage, the duration is capable of infinite individual variation.

(2) One hundred and sixty cases were insufficient to warrant such positive deductions upon an intricate therapeutical problem. In every one of the cases cited by Dr. Knox it was clearly indeterminate whether or no the effect was *post hoc* or *propter hoc*.

Black cohosh had been employed on an extensive scale in large lying-in hospitals in Germany. Every condition for accurate clinical observation had been supplied. Such conditions were: competent observers, numerous cases under absolute control for a sufficient period of time, chemical purity of the drug, and an approximately perfect system of keeping records. Up to the present time results had been of a purely negative character. It was true that Schatz had reported favorably as to the action of the drug in the treatment of certain pathological conditions of the uterus.

Dr. Jaggard did not wish to be understood as dogmatically condemning the drug. The evidence in favor of its action as an oxytocic, as collected from experiments upon the lower animals or from clinical observation, was entirely insufficient to warrant the positive conclusions of the author of the paper. The subject was worthy of further investigation.

(3) He thought the practice of the exhibition of ergot before the completion of the second stage of labor was reprehensible. It was in conflict with the obstetrical principles of the day, as deduced from clinical experience and the nature of the case. This remark was applicable exclusively to physiological labors.

Dr. CHARLES WARRINGTON EARLE had used black cohosh, at the suggestion of Dr. Jones and Dr. Knox, in a variety of cases with negative results. He had about the same number of precipitate labors

<sup>1</sup> *Archiv für Gynäkologie*, 1883, Bd. No. XXI., Heft 1., p. 29.

as occurred in his practice prior to the introduction of the drug. It was possible that he had not employed doses of sufficient size, nor for a sufficient length of time before labor.

Dr. HENRY T. BYFORD wished to enter a protest against all methods of rendering the process of labor shorter. Quick labors were wrong labors as a rule.

Dr. GEORGE M. CHAMBERLAIN had no experience with black cohosh, but he was opposed to the exhibition of ergot before the expulsion of the child in physiological cases.

Dr. KNOX closed the discussion. In reply to Dr. Jaggard, he said that the results of his clinical experience with black cohosh were of such a convincing character that he would continue the exhibition of the drug in the future. In regard to the exhibition of ergot before the expulsion of the child, he did it to save time. The drug was not absorbed until twenty minutes after exhibition, and long before the expiration of that time the child was born. He could not spare the twenty minutes required to secure contraction of the uterus after delivery of child and placenta. In reply to Dr. Byford, he said that, at the present day, there were no physiological labors. Women were not Eves. By the judicious use of a drug like black cohosh, labor was made to resemble the ideal physiological process, as still observed among savages.

II. The Secretary then read the inaugural thesis of Dr. EDMUND J. DOERING (M.D., Chicago Medical College, 1874), entitled

SOME REMARKS ON THE VALUE OF PERMANGANATE OF POTASH IN AMENORRHEA.

After a brief description of the physical and chemical characters of the drug, Dr. Doering discussed its physiological action. Bartholow, who has great faith in the drug, claims that, although it parts with its oxygen with great readiness, this readiness is *not* sufficiently great to prevent the distribution of the gas into the blood. "His opponents deny this, and argue that the organic matter contained in the stomach and mucous membranes is sufficient to appropriate the oxygen of the salt and thus prevent its entrance into the circulation."

Prof. N. Gray Bartlett, a Chicago chemist, gives the following opinion:—

"From the readiness with which the permanganate of potassium is decomposed by organic compounds, it would seem to be ineligible for internal use. When so administered, it is immediately brought into contact, in the stomach, with a relatively large amount of organic matter and must necessarily be very rapidly destroyed, the manganese of the permanganate separating, in all probability, in the form of the hydrated manganese dioxide. The latter compound is an active oxidizing agent, and is possibly capable of exercising in the economy the oxidizing function, which has been ascribed to the permanganate of potassium. It would seem rational, therefore, anticipating the change which follows the administration of the permanganate, to substitute the hydrated dioxide of manganese, which can readily be prepared in a state of purity for medical use.

"Whatever view may be adopted as to the

chemical change which the permanganate undergoes in the human economy, the main question is as to its therapeutic value."

Prof. T. Gaillard Thomas, M.D., in his address to the New York State Medical Association, expresses faith in the value of the drug as an emmenagogue. Dr. Ringer and Dr. Murrell recommend the remedy. Dr. Doering had given the drug a careful trial in thirty cases of amenorrhoea, depending upon anemia and general atony of the sexual apparatus. In about half the cases the observations were unsatisfactory from various causes, that is, inattention to the general directions, want of perseverance in taking the medicine, so that the conclusions arrived at were based upon fourteen cases, in each of which the cause of the amenorrhoea was entirely clear, the remedy carefully and continuously given, and the effect clearly observed.

The cases were tabulated.

(1) Permanganate of potash in doses of from two to four grains is an efficient emmenagogue, if administered for a period of not less than two weeks.

(2) Its administration in doses large enough to be effective is accompanied by severe pain, which frequently necessitates the discontinuance of the remedy, and hence impairs its value as an emmenagogue.

(3) The most efficient method of administering the drug is in capsules, taken midway between meals, and followed by large draughts of some pure mineral water, like Silurian.

Dr. DOERING was elected Fellow of the Society.

REPORT OF THE PROCEEDINGS AT THE THIRTY-SIXTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION AT NEW ORLEANS.

GENERAL MEETINGS.—MEDICAL SECTION.

The thirty-sixth annual session of the American Medical Association opened on the morning of April 28th, under the most favorable conditions of wind and weather. With a delightful breeze, a mild June heat, and the dust laid by timely showers of the day before, there was nothing lacking to personal comfort.

The Association was called to order at eleven o'clock by Dr. SAMUEL LOGAN, of New Orleans, chairman of the Committee of Arrangements. After prayer by the Rev. B. M. Palmer, D.D., the President, Dr. HENRY F. CAMPBELL, of Augusta, Ga., was introduced.

Dr. LOGAN then delivered an address of welcome, after which Dr. CAMPBELL delivered the annual address.

PRESIDENT'S ADDRESS.

After reviewing the records of the various Presidents, and the past work of the Association, he treated more especially: "The relations of the medical profession to tribunals of laws," or more summarily: "The doctor in the courts."

At the present time and in the eyes of most communities, the plane to which the medical deponent and expert has at last gravitated is but little above that of the ordinary, if not the partisan, witness.

The light of scientific truth he sheds is even sometimes suspected of coming with bent and refracted rays through the distorting lens of self-interest and a paid opinion. From circumstances which condition his testimony, he seldom now occupies in this country the honorable position of *amicus curiæ* or friend and instructor of the court on scientific questions, upon which may rest an important judicial decision. He is almost invariably presented as the medical witness or the medical expert in behalf of one side or other of the case upon trial. He is cited to appear as a witness in its behalf more frequently, not because he possesses superior knowledge of the scientific truths about which his testimony is to be conversant; not because his medical opinion *per se* is entitled to more confidence than that of another; but because he is known to hold opinions favorable to the side on which he is to depose. Quite often his only claim to the character of a medical expert depends upon a summons thus conditioned. The reliance upon medical testimony and, in time, confidence and respect for the medical profession must necessarily be depreciated by such exponents of them both.

The three principal positions or attitudes in which, as professional men, we most frequently stand related to the tribunals of law, are: first, as the medical witness; second, as the medical expert; and, third, as a defendant in suits of malpractice.

In each one of these relations it could readily be shown that the medical man labors under disadvantages which do not, in the same degree, embarrass either the testimony or the defence of any other class of citizens. Prussia, recognizing the evils of ignorant and unworthy experts in the medical profession, as well as in all others from which scientific testimony has to be elicited in grave questions pending before the courts, has a toxicologist appointed by the Government, and a permanent commission of experts in matters connected with medical science. In Scotland, medical witnesses are said to deliver their examinations in writing, but are subjected to oral cross-examination before the court; in France, the judges decide who shall act as experts in certain cases, also what questions shall be submitted to them, the answer being returned to the jury in writing; "and practically it is said to have the weight of conclusive evidence." In England, thus far, no system has been adopted. In most of the European courts mentioned there is an incidental protection given to the scientific medical witness from the assaults and indignities offered by the examiner and the advocate.

Practically the private communications from the patient to his medical adviser are the only ones that ever become the subjects of extorted testimony. "As the law now stands, in some of our States, the medical person confided in by his patient has no protection in the law; even if the judge choose to overlook his refusal to appear, to his patient's detriment, the doctor, like any other ordinary witness, may be prosecuted for damages sustained by the party calling him if it can be shown that by the withholding of testimony the party's interests had suffered."

It is, however, in suits for malpractice that the danger and the evil lie, in the course of years,

grown so unpleasantly familiar to the medical profession. The scientific, skilful, and faithful surgeon, particularly should he be known to possess means to meet damages, no less than the ignorant and unscrupulous pretender, is constantly liable to have laid to his charge often the unavoidable results of injuries, as the consequences of either incompetence or neglect.

That portion of the address relating to medico-legal matters was, on motion of Doctor Quinby, of Jersey City, referred to a committee of five, to be appointed by the chair.

Dr. J. G. RICHARDSON, of Philadelphia, read the report of the committee appointed last year to take action on the death of Professor Gross.

Dr. J. S. BILLINGS reported the success of the special committee appointed to secure from Congress an appropriation for the erection of a fireproof building for the Army Medical Museum and Library at Washington.

Dr. Billings reported the action which had been taken concerning the next International Medical Congress, and the Executive Committee, in accordance with resolutions adopted at the last annual meeting of the Association, has invited the Congress to hold its next session in this country and has made arrangements to that effect.

On motion of Dr. Keller, of Arkansas, the report was made the special order for Wednesday at 12 noon.

The report of Dr. Albert L. Gihon, U. S. N., on the subject of the erection of the monument to Dr. Benjamin Rush, was presented, and on motion by Dr. Toner, of Washington, was made the special order for Friday morning.

Several papers were read by title and referred to the chairman of the Section on Surgery, having been received too late to enter the printed programme.

The following gentlemen were made

#### INVITED GUESTS:

Drs. Edward Jones, A. B. Miles, and C. J. Bickham, of New Orleans; A. E. Forte, of Philadelphia; J. J. Gauthereaux, of Welcome P. O., St. James Parish, La.; and James R. Scarborough, of Clinton, Ky.

#### THE DISCOVERY OF ANÆSTHESIA BY SULPHURIC ETHER.

Dr. R. A. KINLOCH, of Charleston, S. C., presented the following resolution from the South Carolina Medical Association:—

*Resolved*, That the delegates from this Association be requested to present to the American Medical Association, at its next session, the report of the committee on the discovery of sulphuric ether made to the Association at its last session, and request that body to take such action on the subject of the report as they in their judgment may determine in view of the claims therein set forth.

On motion by Dr. Beverley Cole, of San Francisco, it was referred to the Section on Practice of Medicine and Materia Medica, with the request that it consider the subject and report to the Association.

The Association then adjourned to Wednesday morning at ten o'clock.

GENERAL SESSION. WEDNESDAY. — SECOND DAY.

The Secretary announced the following

## COMMITTEE ON NOMINATIONS:

John Cochrane, Alabama; R. A. Kinloch, South Carolina; L. P. Gibson, Arkansas; R. B. Cole, California; H. O. Walker, Michigan; C. C. Wyckoff, New York; William Pierson, New Jersey; W. H. Phillips, Ohio; R. S. Sutton, Pennsylvania; D. W. Krouse, Iowa; J. A. White, Virginia; J. H. Murphy, Minnesota; N. T. Nelson, Illinois; T. G. Richardson, Louisiana; C. H. Shackford, Massachusetts; Job W. Smith, Florida; J. B. Robertson, Texas; S. S. Riddell, Wisconsin; E. F. Upham, Vermont; A. Y. P. Garnett, District of Columbia; L. D. Waterman, Indiana; G. W. Baldwin, Kansas; B. F. Coleman, Kentucky; S. C. Gordon, Maine; R. J. Nunn, Georgia; J. McAbran, Wyoming; Joseph R. Smith, United States Army; George Peck, United States Navy; John Godfrey, United States Marine-Hospital Service; D. T. Nelson, Illinois; John S. Lynch, Maryland; G. M. Taylor, Mississippi; Le Grand Atwood, Missouri; R. C. Moore, Nebraska; W. E. Anthony, Rhode Island; D. J. Roberts, Tennessee; J. H. Pipes, West Virginia; C. J. O'Hagan, North Carolina.

Dr. DIDAMA then delivered the address of the chairman of the Section in Medicine.

Dr. R. STANBURY SUTTON, of Pittsburgh, then delivered the address in Obstetrics, on the

## OUTGROWTH OF THE FIRST OPERATION OF OVARIOTOMY,

in which he showed that from McDowell's operation nearly all the intra-abdominal operations in surgery had sprung, and noted carefully the lectures and papers delivered on the subject during the last twelve months. He insisted upon greater care in the surroundings of all abdominal operations, and pointed to the admirable results obtained by John Homans, of Boston, and Robert Battey, of Georgia, both of whom used the carbolic spray. He stated that for himself he did not use the spray, but looked upon cleanliness and Listerism as linked so closely together that they might be said to be inseparable, for Listerism is the gospel of cleanliness. He closed with a tribute to Dr. J. Marion Sims.

Dr. W. C. VAN BIBBER, of Baltimore, read a paper on

## PENINSULAR AND SUB-PENINSULAR AIR AND CLIMATE.

which was intended to give information on winter resorts, especially in regard to Florida.

The special order in regard to the

## INTERNATIONAL MEDICAL CONGRESS

being then in order, Dr. John V. Shoemaker, of Philadelphia, protested against the acceptance of the report, and stated that the American delegates who were present at Copenhagen had been entirely ignored by the Committee. He declared that the Committee had recognized the New Code men. He asked whether the Association had authorized this Committee to elect officers for the Congress. The members of this Committee had ignored the Association, and they have made fun of it for the last ten

or twelve years. He asked what was meant by the statement that a complete programme would be presented at the next meeting? It meant the Councils of the Sections would be filled by a clique.

Dr. F. E. DANIEL, of Fort Worth, Texas, offered the following preamble and resolution:—

*Whereas*, At the last meeting of the American Medical Association a committee was appointed to confer with the International Medical Congress, at Copenhagen, with a view to securing the next meeting of that body, in 1887, at Washington, and to arrange for the said meeting; and

*Whereas*, This Committee, after accomplishing this object, have proceeded, without authority from this body, to appoint the officers of the Congress, which have been published in detail in the *Journal* of the Association and other publications, thus giving the aspect of authoritative action on behalf of this Association; and

*Whereas*, This Association recognizes the Committee as a Committee of Arrangements only, and in so far as the duties of the Committee have been performed, it declines to endorse the said appointments; therefore,

*Resolved*, That the Committee on Nominations be instructed to prepare and present to the Association nominations for the officers of the Congress and its various Sections.

Dr. J. S. BILLINGS, U.S.A., denied *in toto* Dr. Shoemaker's statement that any bargaining was had with any one. No New Code men were consulted by the Committee, unless Dr. Moore, of Rochester, could be considered a New Code man. He called attention to the resolution of last year which appointed the Committee, and gave it the power—if the invitation was accepted—to add to its membership, to perfect its organization, to elect its officers, and to act as an Executive Committee, with full power to make all necessary and suitable arrangements for the meeting, and to solicit funds for this purpose. This committee, which consisted of Drs. Austin Flint, of New York; H. F. Campbell, of Georgia; L. A. Sayre, of New York; J. Minis Hays, of Philadelphia; Christopher Johnston, of Baltimore; George J. Englemann, of St. Louis; J. M. Browne, U.S.N., and J. S. Billings, U.S.A., presented the invitation at Copenhagen, and, upon its acceptance, were constituted the Organizing Committee of the Congress. This Committee, under the power given it, enlarged its number to twenty-five, so that it should be representative of every section of the country. It then proceeded with the necessary preliminary work for the organization of the Congress, which was done, thus early, in accordance with the advice of the Committee of Arrangements of both the London and Copenhagen Congresses. The Committee had acted to the best of its ability and with honest motives. He hoped that no hasty action would be taken to overthrow the reported work of the Committee, because such action would cause an unfortunate delay in the organization of the Congress, and was calculated to create an unfavorable impression abroad.

Dr. J. F. GAUREL, of Piqua, Ohio, complained that the delegates had not been consulted at Copenhagen by the Committee.

Dr. J. M. KELLER, of Hot Springs, Arkansas, considered that the Committee was responsible to the Association for its action, and had overlooked its responsibility. He offered the following amendment to Dr. Daniel's motion:—

*Resolved*, that the committee appointed by the American Medical Association to arrange for the meeting of the International Medical Congress in 1887 be enlarged by the addition of members from this Association, one from each State and Territory, and from the Army and Navy, and Marine-Hospital Service, and the District of Columbia, to be appointed by the present presiding officer, Dr. J. S. Lynch, of Baltimore, first vice-president, and that this committee thus enlarged shall proceed to review, alter, and amend the action of the present committee as it may deem best.

Dr. COLE, of California, said that the committee had erred, though probably not intentionally. He was strongly opposed to the exaltation of New Code men.

Dr. WILLIS P. KING, of Sedalia, Mo., said that he could not doubt the honesty of the members of the committee, but they had entirely neglected the West and South and had only considered the North and East.

Dr. SHOEMAKER repeated that the New Code men had made threats at Copenhagen.

Dr. DANIEL said that Texas had been ignored in the composition of the committee.

Dr. D. D. SANDERS, of Memphis, Tenn., moved as an amendment that the report of the committee be accepted and the committee continued.

Dr. J. B. ROBERTS, of Philadelphia, said it would be better to endorse the action of the committee than to publish the dissensions that exist at home. A motion to adjourn was lost, 41 to 360. Dr. Saunders's resolution was lost, 88 to 129. Dr. Keller's substitute was adopted.

#### THURSDAY.—THIRD DAY.

The amendment to the By-laws providing that each Section shall elect its own officers which was offered last year by Dr. Foster Pratt, of Michigan, was called up, and its further consideration postponed till next year.

Dr. N. S. DAVIS read the report from the Standing Committee on

#### METEOROLOGICAL CONDITIONS AND THEIR RELATION TO THE PREVALENCE OF DISEASES.

Dr. Davis also read a report of the Committee on the

#### COLLECTIVE INVESTIGATION OF DISEASE.

Dr. Davis also submitted the report of the Committee appointed last year to give an authoritative explanation of certain clauses of the Code in the following preamble and resolutions:—

*Whereas*, Persistent misrepresentations have been and still are being made concerning certain provisions of the Code of Ethics of this Association, by which many in the community, some in the ranks of the profession, are led to believe its provisions exclude persons from professional recognition simply because of difference of opinion or doctrine; therefore be it

*Resolved*, That Clause I., Article IV., in the National Code of Medical Ethics is not to be interpreted as excluding from professional fellowship, on the ground of difference in doctrine or belief, those who in other respects are entitled to be members of the regular medical profession, neither is there any

other article or clause in said Code of Ethics that interferes with the exercise of the most perfect liberality of individual opinion and practice.

*Resolved*, That it constitutes a voluntary disconnection or withdrawal from the medical profession proper to assume a name indicating to the public a sectarian and exclusive system of practice, or to belong to an association or party antagonistic to the general medical profession.

*Resolved*, That there is no provision in the National Code of Medical Ethics in any wise inconsistent with the broadest dictates of humanity, and that the article of the Code which relates to consultations cannot be correctly interpreted as interdicting, under any circumstances, the rendering of professional services whenever there is pressing or immediate need of them; on the contrary, to promptly meet the emergencies occasioned by disease or accident and to give the helping hand of assistance without unnecessary delay is a duty fully enjoined on every member of the profession, both by the letter and spirit of the entire Code, but no such emergencies or circumstances can make it necessary or proper to enter into professional consultation with those who have voluntarily disconnected themselves from the regular medical profession in the manner indicated by the preceding resolution.

Signed, N. S. Davis, Chicago; A. Y. P. Garnett, Washington; H. F. Campbell, Augusta, Ga.; Austin Flint, Sr., New York; J. B. Murdock, Pittsburgh.

This report was adopted unanimously as an interpretation of certain clauses in the Code.

The address in Surgery was read by Dr. DUNCAN EVE, of Nashville.

The Treasurer's report showed a balance of \$932.11 in the treasury.

#### THE COMMITTEE ON PUBLICATION

presented its report in which it stated that the *Journal* is free from debt. The number of members entitled to receive it is 3,050, the number of subscribers is 850, and the exchanges and advertisers require 120 more. The total number of copies published is 4,200, and the probable income is not much less than \$6,000. The total income from dues is \$21,000. The expenses are \$12,000, not including the expenses of the editorial office. The Committee had unanimously requested Dr. Davis to continue as editor.

Dr. Davis spoke at length of the difficulties in conducting the *Journal*. He opposed increasing the annual dues, as it would have the effect of decreasing the number of members—especially of new members. He said that in ten years the *Journal* would stand at the head of medical periodicals.

Dr. HARVEY REED, of Ohio, moved that the Association offer yearly in each Section prizes for the first and second best papers containing original research. Adopted.

Dr. J. B. ROBERTS, of Philadelphia, from the Section on State Medicine, offered a resolution recommending the appointment in each State of an examining board whose certificate shall be a license to practise. Laid on the table temporarily.

The Committee appointed to consider the advisability of erecting

#### A MONUMENT TO BENJAMIN RUSH,

in the city of Washington, recommended that such monument be erected by dollar subscriptions.

The Nominating Committee then presented the following list of

#### OFFICERS FOR THE ENSUING YEAR:

*President*.—William Brodie, M.D., of Michigan.  
*Vice-Presidents*.—Samuel Logan, M.D., of Louisiana; A. Y. P. Garnett, M.D., of the District of Columbia; Charles Alexander, M.D., of Wisconsin, and W. F. Peck, M.D., of Iowa. *Section of Medi-*

*cine.*—J. T. Whittaker, M.D., of Ohio, chairman; B. L. Coleman, M.D., of Kentucky, secretary. *Section of Obstetrics.*—Seth C. Gordon, M.D., of Maine, chairman; J. F. Y. Paine, M.D., of Texas, secretary. *Section of Surgery.*—N. Senn, M.D., of Wisconsin, chairman; H. H. Mudd, M.D., of St. Louis, secretary. *Section of Ophthalmology.*—Eugene Smith, M.D., of Michigan, chairman; J. F. Fulton, M.D., of Minnesota, secretary. *Section of Diseases of Children.*—W. D. Haggard, M.D., of Tennessee, chairman; W. B. Lawrence, M.D., of Arkansas, secretary.

*Dental and Oral Surgery.*—Dr. J. H. Marshall, Illinois, chairman; Dr. J. E. Baldwin, Illinois, secretary. *Committee on State Medicine.*—Dr. J. S. Rauch, Illinois, chairman; Dr. F. E. Daniel, Texas, secretary. *Committee on Necrology.*—Dr. J. M. Toner, Washington, chairman.

*Judicial Council.*—Drs. R. A. Kinloch, South Carolina; D. D. Saunders, Tennessee; T. G. Richardson, Louisiana; D. A. Ketchum, Alabama; George Beard, West Virginia; J. M. Toner, District of Columbia; A. M. Pollak, Pennsylvania.

*Place of Meeting.*—St. Louis, Mo., on the first Tuesday in May, 1886.

The following members were added to

#### COMMITTEE ON INTERNATIONAL CONGRESS:

Drs. D. A. Linthicum, Arkansas; George A. Ketchum, Alabama; A. R. Smart, Michigan; J. V. Shoemaker, Pennsylvania; F. A. Sim, Tennessee; J. W. McLaughlin, Texas; A. Y. P. Garnett, District of Columbia; S. C. Gordon, Maine; John S. Lynch, Maryland; Ellsworth Eliot, New York; C. C. Scott, Ohio; W. C. Dabney, Virginia; Nicholas Senn, Wisconsin; Robert Battey, Georgia; J. W. Dupree, Louisiana; W. E. Anthony, Rhode Island; R. D. Murray, Florida; E. P. Cook, Illinois; R. B. Cole, California; Charles Denison, Colorado; F. W. Beard, Indiana; D. W. Stromont, Kansas; L. P. Bush, Delaware; A. H. Wilson, Massachusetts; William Pierson, New Jersey; R. A. Kinloch, South Carolina; W. H. Watson, Kentucky; E. French, Minnesota; N. F. Essig, Missouri; R. C. Moore, Nebraska; G. Baird, West Virginia; Surgeon-general Murray, United States Army; Surgeon-general Gannett, United States Navy; Surgeon-general Hamilton, Marine-Hospital Service.

The Secretary announced the following committee on that part of the President's address relating to forensic medicine: Drs. Quinby, of New Jersey; Scott, of Cleveland, Ohio; Dawson, of Cincinnati, Ohio; Daniel, of Texas; Shoemaker, of Philadelphia; Foster and Campbell, of Augusta, Georgia.

#### MEDICAL SECTION.—FIRST DAY.

At 3.30 p.m. the Section of Practice of Medicine assembled in Tulane Hall, with Dr. H. D. Didama, of Syracuse, N. Y., as chairman.

The first paper presented was upon

#### THE TREATMENT OF CARBUNCLE WITHOUT INCISION.

by DR. L. DUNCAN BULKLEY, of New York. As a text for his article, Dr. Bulkley reported the case of a man fifty-six years of age, who had a carbuncle upon the back of his neck. During its development

this carbuncle reached the size of four inches in diameter, and the case was complicated by the presence of glycosuria.

The treatment pursued was as follows:—

*Internally.* Patient was given quarter-grain sulphide of calcium pills every two hours, irrespective of meals. The following mixture was also prescribed in teaspoonful doses after each meal:—

R. Magnesie sulphatis . . . . .	5 vi
Ferr sulphat. . . . .	5 j
Acidi sulph. dil. . . . .	5 iij
Syr. Zingib. . . . .	5 j
Aque ad. . . . .	5 iij

*Locally.* No poultices were allowed, but the following mixture was spread thickly on the woolly side of lint and applied to the inflamed part:—

R. Ext. Ergotae fl. . . . .	5 ii
Unguent aque Rose . . . . .	5 iij
Zinci Oxid. . . . .	5 j

This dressing was to be renewed twice daily, or oftener if there was much discomfort. The patient was allowed to attend to his business, which he did without much complaint. From the beginning of the treatment the pain and soreness of the carbuncle began to diminish, although the tumor itself increased in size.

This constituted the whole of Dr. Bulkley's treatment. The points which he attains by this method are: the careful avoidance of unnecessary irritation to the inflamed surface; the avoidance of all warm and moist applications, such as poultices, which he thinks increase discomfort; the avoidance of painful surgical proceedings; the perfect protection of the inflamed part by a soothing ointment, which is always gratefully acknowledged by the patient. The system is sustained, not by stimulant food and medicine, but by securing a healthy performance of the functions of the system with nutritious and healthful food and fresh air.

Dr. Bulkley has employed this treatment in many cases, and the advantages which are observed to follow it are: (1) A comparatively short duration of the entire process. (2) A comparatively small amount of pain. (3) A comparatively small amount of scarring. (4) The avoidance of a surgical operation. (5) The avoidance of detention in bed.

#### DISCUSSION.

DR. JAMES F. HERRICK, of Richmond, Indiana, cordially indorsed the suggestions of the paper. He had long abandoned the use of crucial or other incisions for carbuncles, nor did he employ poultices unless driven to it by the interference of friends. During the last year he has treated carbuncles by the gentle inunction of oleate of morphia applied every three hours. He reported several cases where this plan of treatment had not only diminished the sensitiveness of the swelling, but had also apparently aborted the disease. The carbuncle ceased to develop, diminished rapidly in size, and disappeared. Dr. H. had not accumulated a large enough number of cases to make any definite assertions as to the infallibility of the remedy, but it had appeared to work in a wonderful manner.

DR. SAVAGE, of Jacksonville, paints a zone of cantharidal collodion, from one half to an inch in

width, around every carbuncle. A blister is formed, and the result is great relief from pain and a relatively comfortable progress of the disease.

In closing the discussion, Dr. BULKLEY said he never opens a carbuncle, even at an advanced stage, when its contents are liquid, as shown by fluctuation. Nature provides a way for the safe discharge of the pus, whereas an incision exposes the patient to the possibilities of absorption and subsequent danger.

The second paper of the day was presented by Dr. ASA F. PATTEE, of Boston, Mass., on the

#### PERCUTEUR: ITS USE IN DISEASES OF THE NERVOUS SYSTEM.

This paper consisted of a *résumé* of Dr. J. Mortimer Granville's book on "Nerve Vibration and Excitation," with notes upon cases from his own practice. Dr. Pattee exhibited a pereuteur which he had had constructed for his own use, and in which he employed electricity as the motive force for the hammer.

The third paper, upon

#### HYDATID TUMORS OF THE BRAIN.

was by Dr. N. HARVEY REED, of Mansfield, Ohio. This paper contained the clinical history of four peculiar cases with the post-mortem discovery of cystic tumors in the brain. These cysts, Dr. Reed maintained, were hydatid tumors, and he asserted that he had found microscopic evidence of the same, although he presented no such evidence to the Section. This paper evidently aroused considerable doubt in the minds of those who heard it, and Dr. J. T. Whittaker, of Cincinnati, expressed regret that the microscopic evidence had not been presented with the paper.

Dr. WHITTAKER has made diligent search for hydatid specimens in his section of Ohio to use for clinical teaching, and he had met with but little success. He suggested that apoplectic cysts into the substance of the brain may closely resemble hydatid tumors. The reading of this paper will inevitably occasion a closer scrutiny of such cysts in the future.

The last paper of the day was read by Prof. J. T. WHITTAKER, of Cincinnati.

#### AN ATTEMPT AT THE RADICAL TREATMENT OF TUBERCULOSIS.

Dr. WHITTAKER said: "It may be taken for granted that every one now believes the disease (tuberculosis) to be a mycosis. With the double purpose of directly attacking the cause of this disease with an antimycotic agent, and of producing the imitation which might result in proliferation of the connective tissue of the lung, I have made a number of parenchymatous injections into the lungs with solutions of the mercuric bichloride of varying strength."

He chose patients in whom the disease existed in what is commonly called the first stage. He stated that seven years ago he lost a patient while aspirating a large cavity in the left upper lobe, before the class. "I may state parenthetically that I had upon this occasion to appear before a coroner and fortify my position with the citation of an array of cases in which this operation was successfully performed,

though, as was later ascertained, with no permanent benefit in any case."

The essayist then related his observations upon five patients carefully selected where accurate thermometric records were kept, and all points of history were noticed with regard to cough, night-sweats, appetite, condition of bowels, and weight. The bichloride was injected into the lung, daily, at a depth of four to six inches, in quantities varying from one thirty-second to one eighth of a grain. At the same time all patients inhaled from an atomizer a solution of the bichloride with common salt, three times daily for five weeks. There was, as a result of this treatment, no change whatever in the course of the disease. What fluctuations were observed were of the same character precisely as before. Dr. Whittaker next spoke of the value of the bichloride as an antimycotic agent in general, and sought to account for its failure in tuberculosis.

To render the bichloride less painful and more permanent, as well as to secure a preparation more easily absorbed and assimilated, it has been proposed by Stern Rader and Gschirhagl to make of it a neutral solution, by the addition of common salt in the proportion of ten parts of salt to one of the sublimate. This also renders the solution less productive of inflammatory *dépôts*.

Regarding the efficacy of the sublimate in destroying the tubercle bacillus, the experiments of Hollander with tuberculous sputa show that small quantities of no disinfectant suffice to render such sputa innocuous. To absolutely destroy all tuberculous germs, it requires a proportion of two tenths of one per cent. corrosive sublimate. To produce the same effect with carbolic acid requires a strength of three per cent. Two fifths of one per cent. equals practically one grain to the ounce. A hypodermic syringe full of this solution contains about one eighth of a grain. This quantity can be injected with impunity into the lungs.

In conclusion, Dr. W. said: "But the question arises whether the destruction of a large mass of the bacilli tuberculosis will cure the disease. Will not a few, which must under any circumstances escape, continue to multiply as before? Or, will not the soil remain just as fertile to the reception of new seed? The mycologists themselves do not, as a rule, look with favor upon experiments of this kind. Yet clinicians can never be content with prophylaxis alone. There is still hope of effecting by drugs such chemical changes in the lung tissue as will make it infertile to the growth of the bacilli, and bring about the condition which takes place in the process of natural recovery."

#### SECOND DAY.

The first paper of the day, before the Medical Section, was offered by AUSTIN FLINT, M.D.

#### A UNIFORM NOMENCLATURE OF PHYSICAL SIGNS WHICH OCCUR IN CONNECTION WITH THE RESPIRATORY SYSTEM.

The International Medical Congress in London, in 1881, recognizing the dire confusion and frequent contradiction of terms applied to physical signs in different countries, appointed a committee of five to consider the subject of a uniform nomenclature for

these signs. This committee consisted of Dr. Flint (chairman), of New York; Drs. Mahomed and Powell, of London; Professor Ewart, of Berlin; Professor D'Espine, of Geneva.

The unfortunate death of Dr. Mahomed deprived the committee of an enthusiastic and able worker. Since his death Professor Lépine, of Lyons, France, and Professor Trier, of Copenhagen, have been added to the committee.

Professor Flint's paper at the meeting was simply a provisional statement of these facts and included the accompanying tabulated list of such terms as the committee have already agreed upon. Professor Flint hopes that those who are interested in this subject in America will communicate to him such suggestions as may occur to them.

TABULATED LISTS

Of terms proposed by the British members and the American member of the Committee appointed at the meeting of the International Congress in 1881, to report on a uniform nomenclature of physical signs which occur in connection with the respiratory system.

PALPATION.

BRITISH LIST.	AMERICAN LIST.
DRS. POWELL AND MAHOMED.	DR. AUSTIN FLINT.
1. Vocal fremitus.	Vocal fremitus.
2. Rhonal fremitus.	Rhonal fremitus.
3. Friction fremitus.	Friction fremitus.

PERCUSSION.

1. Tympanitic resonance.	Tympanitic resonance.
2. Amphoric resonance.	Amphoric resonance.
3. Diminished resonance. Dulness.	Diminished resonance. Dulness.
4. Absence of resonance. Flatness.	Absence of resonance. Flatness.
5. Increased resonance.	Increased or vesiculo-tympanitic resonance.
6. Bell sound. <sup>1</sup>	(Not included.)

AUSCULTATION.

First Group. Varieties of Breath Sounds.

1. Exaggerated. Syn. Puerile. Compensatory. Supplement. ary.	Exaggerated, etc.
2. Diminished. Syn. Feeble.	Diminished, etc.
3. Suppressed. Syn. Absence of breath sound.	Suppressed, etc.
4. Prolonged expiration. General or local.	Prolonged expiration. High or low in pitch.
5. Interrupted inspiration. Syn. Jerking, wavy, cog-wheeled.	Interrupted inspiration, etc.
6. Tubular. Syn. Bronchial.	Tubular. Bronchial.
7. Vesiculo-tubular. Syn. Broncho-vesicular. Harsh, coarse, sub-tubular.	Broncho-vesicular. Syn. Vesiculo-tubular.
8. Amphoric.	Amphoric.
9. Cavernous.	Cavernous

Second Group. Adventitious Sounds.

1. Rhonch. Dry rousant sounds. (a) Sonorous, (b) Sibilant.	Rhonch or dry bronchial rales. (a) Sonorous, (b) Sibilant.
2. Stridor.	Stridor.
3. Rales. Syn. Bubbling rales, etc. (a) Medium, (b) Large. High or low in pitch.	Moist or bubbling rales. (a) Medium, (b) Large, (c) Small. High or low in pitch.
4. Gurgling.	Gurgling.
5. Clicking.	Clicking.
6. Crepitation. Syn. Crepitant rale.	Crepitant rale or crepitation.
7. Metallic tinkling.	Metallic tinkling.
8. Splash.	Splash.
9. Friction. (a) Dry, (b) Moist.	Friction.

<sup>1</sup>This term is applied, by some English writers, to a sound produced by percussion, a coin being used as a pleximeter, and then applied to the chest. It is supposed to be characteristic of pneumonia thorax.

Third Group. Varieties of Voice Sounds.

1. Increase of vocal resonance.	Increase of vocal resonance.
2. Diminution or absence of vocal resonance.	Diminution or absence of vocal resonance.
3. Bronchophony.	Bronchophony.
4. Pectoriloquy.	Pectoriloquy.
5. Egophony.	Egophony.

Dr. J. V. SHOEMAKER, of Philadelphia, then read a paper on

THE HYPODERMATIC INJECTION OF OIL.

Experimental and clinical observations have taught us that oils that cannot be swallowed or are rejected by the stomach can be absorbed by innunction and subcutaneous injection, and numerous instances of the absorption and assimilation of oil and fat by the skin also have been reported, and their value in certain conditions, employed in this way, has been fully recognized; but the more rapid and effective use of these agents, subcutaneously, while known, has had little or no practical application.

Menzel and Perco<sup>2</sup> first demonstrated the subcutaneous absorption of fat by injecting an ounce of it in a third state under the skin of a dog, and in the course of forty-eight hours it disappeared, without leaving any local effect. The first practical application of this discovery was probably made by Krueg<sup>3</sup> on an insane patient who refused to eat. Subcutaneous injections of olive oil, twice daily, were then administered, affording sufficient nourishment to keep the patient in good bodily vigor. At the end of a month he was induced to take his food in the natural way, and the injections were discontinued.

Shortly after this announcement of the practical effects in Krueg's case, a most important result from hypodermatic alimentation in a case of gastric ulcer was reported by Dr. James T. Whittaker, of Cincinnati, Ohio. According to Dr. Whittaker's report,<sup>4</sup> after exhausting other medication, the patient was given subcutaneous injections of drachm doses of milk, alternated with beef extract, every two hours for three days; the temperature declined, the pulse became stronger, and the existing pains and delirium disappeared. The milk and beef extract not being well borne by the skin, cod-liver oil was substituted for them, two drachms being given every two hours for two days, and one day as much as eight ounces was thus introduced. Two abscesses formed from the milk, but no ill effects followed the oil, which was well borne; its introduction was also free from pain.

The inability of some of his patients to bear medicine by the stomach, induced the reader, a few years ago, to test thoroughly the subcutaneous absorption of oil, and the effects which followed its use in a number of diseases were highly gratifying.

Oil can be used subcutaneously alone, or combined with other suitable agents that can be easily dissolved in it. It is a valuable menstruum for suspending in it other drugs for hypodermatic use. It can be given in connection with a suitable diet, and even with other medication by the mouth, or it can be used alone for alimentation. Oil deposited in this way in the tissues is absorbed, and is, no doubt, assimilated and will alone keep up the

Wiener Medizinische Wochenschrift, April 17, 1879.  
Wiener Medizinische Wochenschrift II, August 12, 1879.  
<sup>3</sup>Hypodermatic Alimentation, by Dr. James T. Whittaker. Cincinnati Chronicle, January 22, 1876.

nutrition of the body. It is especially useful in diseases of the alimentary canal, as well as in all affections depending upon deficient nutrition. It will very often overcome an impoverished state and give tone and vigor to the system.

For a purgative action, one or two injections of a drachm or two of castor oil usually suffices, but for a nutritive effect the same quantity of one of the bland nourishing oils, for example, cod-liver or olive oil, should be administered two or three times daily. In the event that alimentation is depending solely upon the injections, they should be given about every two hours.

For the purpose of giving oil hypodermatically a large syringe, provided with a needle of good calibre should be used, and the instrument should have a capacity of from two to eight drachms. The injections can be made in almost any part of the body well provided with subcutaneous cellular tissue, into which the oil should always be thoroughly deposited.

### Recent Literature.

*The Law and Medical Men.* By R. VASHON ROGERS, Jr., Barrister-at-Law. Toronto and Edinburgh: Carswell & Co. 1884.

This book is designed for the convenient reference of practitioners of the two professions — medicine and law, but appeals especially to medical practitioners. The different chapters treat of such subjects as Fees, Who Should Pay the Doctor, Who may Practice, Negligence and Malpractice, Criminal Malpractice, Professional Evidence, Medical Experts, etc. There is a table of cases cited. The laws and decisions of courts in the United States, as well as those of Great Britain, are referred to. The book is handy for reference, and, we suppose, as far as it goes, is reliable. It is cheaply got up and the printing is, in some places, careless.

*Medical Diagnosis. A Manual of Clinical Methods.* By J. GRAHAM BROWN, M.D. Second edition, illustrated. Birmingham & Co. 1884.

This attempts to condense into 270 pages, small-octavo, a description of the signs and symptoms of disease, and to show what is their value from a diagnostic point of view. There is a demand for such attempts, and the Edinburgh school of teachers, with their competitive experience in extra-mural classes, should be able to satisfy that demand as well as any others, but the value of such attempts, even when well done, is very questionable. The present edition is cheap bookmaking, and can be called illustrated only by courtesy.

*Handbook of Diseases of the Skin.* Edited by H. V. ZIEGLER, M.D. New York: William Wood & Co. 1885.

This translation of the fourteenth and last volume of Von Ziemssen's "*Handbuch der speciellen Pathologie und Therapie*" is issued as a sort of "extra dividend" to the original subscribers to the whole series. It is a good and somewhat abridged trans-

lation of a valuable book, the most complete work upon Dermatology which has yet been published, being the combined product of the writing of various men distinguished as paying especial attention to this branch of medicine. G. H. T.

*Minor Surgical Gynecology.* By PAUL F. MUNDÉ, M.D. Second edition, revised and enlarged. New York: William Wood & Co. 1885.

We are very glad to see a second edition of this book. When it first appeared as one of Wood's Medical Library Series, its merits were so conspicuous that we regretted it could not be bought separately so as to be within the reach of all, and that its dress was unworthy of it.

Both of these defects have been happily remedied by this second edition. It now comes with type, illustrations, and binding worthy of its contents, and can be had separately. It is not necessary to speak of its value as a gynecological work. Suffice it to say it occupies a field of its own and fills an important gap in the literature of this subject. Its very minuteness of detail is its strong point. It tells the general practitioner a thousand and one little facts of practical importance which other more pretentious books omit, and which make all the difference between knowing and not knowing how to do a thing.

The author has in this edition judiciously pruned and emended, and has given us in addition a chapter on some of the more common operations on the cervix and vagina, notably those for laceration of the cervix and for ruptured perineum. This adds to the value of the book, for these operations are fast becoming common property of the profession.

It would be impossible to read a book of this size and elaborateness without finding numerous points where one has to disagree with the author, but these are usually of minor importance, and taken as a whole it deserves high praise for its completeness, conservatism, clearness of statement, and catholicity of opinion.

Many of the illustrations are very good, and we are glad to see some of the old veterans discarded. They have so long done service they deserve a rest. We can cordially recommend the book to the profession in general, feeling sure that not only specialists but all practitioners will find its perusal profitable. F. H. D.

— A convict in an English prison recently died shortly after being taken off the treadmill, and the inquest developed the fact that he had suffered from heart disease. The high death-rate in some of the English prisons where this punishment is employed suggests that perhaps the criminal class, as a whole, by reason of dissolute habits, exposure, etc., followed by a removal of stimulants and subjection to prison discipline and low diet, are liable to degeneration of the muscular fibres of the heart, so that severe exercise like that of the treadmill becomes injurious and even dangerous. In view of the uselessness of this punishment intrinsically and upon a reformatory standpoint, its abolition would seem to be desirable.

**Medical and Surgical Journal.**

THURSDAY, MAY 7, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by CUPPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM AND COMPANY,

283 WASHINGTON STREET, BOSTON, MASS.

**MEETINGS OF THE AMERICAN MEDICAL AND SURGICAL ASSOCIATIONS.**

THE United States has, taken in its length and breadth, a system—one might even say a want of system—of medical education which is, to say the least, not the best that could be imagined; but notwithstanding some very obvious defects it presents some most admirable results in the character of its graduates.

The surgical work done in this country in the last twenty-five years may well be regarded with pride. A long list of surgeons might easily be made out that would compare favorably with a similar list from any country in the world. A congress of American surgeons ought to produce a series of papers and debates that would attract attention everywhere. But it is, perhaps, easier here than elsewhere to fall into ways that will utterly destroy the usefulness of such an association, and it is not too early to utter a word of warning. The great extent of our country makes it necessary that particular attractions and few chances of being bored should be offered to draw together the best class of men.

To insure success in a surgical association the following would seem to be essentials:—

Careful selection of members.

Meetings held in a place of interest and at a proper time of year.

A careful selection of papers, and their restriction to a good a time as is consistent with clearness.

A good debate kept to the point, and a proper restriction of the time occupied by each speaker.

Many papers which contain what is well worth stating in five or fifteen minutes may empty the seats of a single session and prevent an adequate attendance for years afterward. The same may be said of lengthy comments on papers interesting in themselves. Probably a good discussion is the most entertaining thing that can be presented to a medical society. The free interchange of thought between men who have worked independently at the same

subject, with the same object in view, is sure to be of value, and such a discussion best meets the purpose of such an organization as we are considering. That such a discussion may be good it is necessary that members shall know beforehand the points to be discussed, and that no one man shall monopolize the time at the expense of others equally well posted as himself.

To meet such requirements a committee of arrangements must be perfectly ruthless in the slaughter of all that is tedious, trite, or worthless. Even the best men may ride hobbies to the distress of their associates, and need to be restrained for the best good of all; much more is it necessary to restrain those men whose hobbies have gained the control of their riders. Much may also depend upon the presiding officer, who should execute the rules of debate in an impartial, but in the strictest, manner.

We have no wish to depreciate the work of the Surgical Association nor to criticize the papers, but a comparison of our own Surgical Congress with the French and German shows many points in which our countrymen may profit. Nor do our marks apply alone to the Surgical Association. They are equally applicable to other National and State Societies. In a body so given over to medical politics as the American Medical Association, where there is such a struggle for sectional and personal representation in all departments and in all details, there is little room to expect much progress toward the improvements we have outlined, at least in the general meetings. The work of the Sections promises more at the present and in the future.

As the reports of the general meeting at New Orleans show, the Medical Association has done its utmost to make a mess of the proposed International Medical Congress at Washington in 1887. Representation on Committees would be a poor and barren substitute for an International Congress.

The Association has, we cannot but think, made another mistake in not adhering to its last year's resolve to meet in Washington every second year.

It seems so perfectly possible to make the American Surgical Association the professional and scientific peer of any similar association in any country that friendly criticism is neither ungracious nor superfluous. A step in the right direction was taken by the resolution that names of candidates for admission must be accompanied by a statement of official positions held, writings, and the claims upon which the application is based.

It was also determined to limit the time allowed for a paper to one hour. We cannot but think the time too long, though it is a great advance to establish a limit at all. It is not necessary for the speaker to enter into every detail. The minutiae of the observations that go to prove the truth of the speaker's assertions may well be left for the printed paper. It is sufficient for the speaker, and he should

be a speaker rather than a reader, to show that which is new, to bring into relief the striking point of the communication, and leave the tedious figures to be studied at leisure in the future.

We do not find fault from the mere love of fault-finding nor from a desire to disparage the work of our societies, but from an ardent and patriotic desire to see them raised to a higher standard, and because we believe that faults must be seen to be corrected. Our societies fall short of the standard which American societies ought to reach. We have pointed out the manner in which we believe an improvement may be made, not because we believe ourselves alone gifted with the power of prophecy, but because it is necessary that the truth be told if our societies are to flourish. We have spoken what we believe to be widely felt. We should be glad if our suggestions led to discussion and amendment, and should welcome improvement however brought about.

#### OVERPRESSURE AT SCHOOL AS IT AFFECTS GIRLS.

THE subject of overpressure at school, as the readers of the JOURNAL are aware, has attracted a great deal of attention of late in England, and the discussion appears to have occasioned a good deal of bitterness, partisanship, and hasty assertion. The subject is, of course, an old one in New England, and probably every schoolboard has in a measure been obliged to consider it, but at the present time, when the courses of study are so varied and the educator is obliged to seek for excellence for his pupils in many departments, the risks of overwork are greater than ever.

The editor of one of our most estimable medical contemporaries in New York, in commenting on the subject, stated lately that American physicians do not meet cases alluded to by English writers. We are not to infer from this that the metropolis is to be regarded as that happy land where it is an accepted fact that ignorance is bliss, but rather to believe that our brother has generalized from his own experience, which apparently has not led him to the examination of schoolchildren. If the girls of the high and normal schools on their way to and from school, or if the freshman classes at our female colleges, recruited from the training-schools in different parts of the country, are attentively observed, the query forces itself upon the mind of the thoughtful as to whether our present civilization, which prides itself so much on attempts at intellectual development, is not really as barbaric as the social state of the flat-headed Indians who attempt to increase their "long-headedness" by squeezing the antero-posterior diameters of their crania. We fear the educator, in his theoretical zeal, has overlooked the most important factor of all—the making of good citizens and good parents.

The following instance may serve to point the moral, and though an extreme, is not an exceptional case.

A young girl of sixteen, of a healthy heritage, was brought into the consulting-room of one of our Boston physicians for a slight lateral curvature. She never had been sick, she did not suffer from headaches or any of the functional disturbances sometimes seen in growing children. Her growth had been rapid, and she was pale, thin, and lacked the vigor of health. An inquiry brought out the fact that at her school she spent five hours a day, besides five hours' study out of school hours, stimulated to extra courses by ambition and the prospect of promotion.

A growth of three inches in a year, combined with ten hours' daily nervous strain, are components which will, as certainly as the formula of  $2+2=4$ , produce an impairment of health; a diminution of force which, coming in the growing years, is so much taken from the eventual sum total of vital energy. The studies which were the most of a burden to this young girl were Greek and algebra, and although the parents, if forced to choose, would agree that their daughter should forego the pride of possessing a knowledge of Greek, if that must be coupled with a certain amount of physical misery, yet nothing short of a dire necessity could justify the girl in falling behind her class or the standard imposed by emulation. And there are parental aspirations of Wellesley or Vassar or the Harvard Annex.

Such experiences lead us to believe that the root of the trouble is not so much in the school system as in the community itself, which, after all, creates the school system. With a certain amount of elasticity of requirements and an improved supervision of scholars, much of the evil of advanced courses and increasing stimulation could be avoided, provided the home influence were in the right direction. The ill effects are seen chiefly among the girls; for it is tacitly admitted that, books or no books, "boys will be boys," and the boy is largely an animal; but the American mother of the day not only wishes to stamp out what there may be of the animal in her daughter, to give her conventional manners, but, in view of the lottery of American life, to teach her to support herself and also to shine socially as a possible mistress of the White House; and all this preparation is to be done during the pre-matrimonial years. Out-of-door sports are discouraged, and musical or intellectual preëminence considered desirable. Furthermore, among the girls themselves in a certain number, the desire for distinction, the innate femininity, repressed by circumstances from finding vent in coquetry, prompts to attracting attention and admiration for proficiency as amateur musicians, for rank at school, for winning prizes in female colleges, for success in professions. Such a system of education may produce, in some instances, good results and give us future George Eliots,

Maria Mitchells, Mary Somervilles, Putnam-Jacobis, etc., yet the records of the nervous wards and the lists of the nervous prostrationists show that the success of a few individuals has been bought for the public at the price of many shattered lives of unsuccessful imitators. Certainly every physician will admit that ignoring the corporeal and stimulating the spiritual in young growing girls is the worst of management, and even if likely to produce creatures to be admired by the lovers of the pre-Raphaelite models for Burne-Jones and Rosetti, is sure to result in very poor material for the lying-in room or the nursery.

What in our community is especially needed in regard to women is the better *physical* education of girls. A mother should be as much ashamed to bring up a flat-chested, round-shouldered daughter, to be a candidate for the Adams or other Nervine Institutions, as if she brought her up unable to read or write. The introduction of any out-door game suitable for girls, and enjoyed by them, as baseball is by boys, would be an incalculable blessing, before which the joys of Greek and the aspirations for professional careers would be dust and ashes to the coming generation of mothers and the prospective generation of children.

A certain, and by no means small, proportion of our young women seems to be going through the same craze about mental forcing and professional careers which afflicted our young men of previous generations and which with them was responsible for much ill health. Fortunately a revival of athletics and sports, the war, and the development of more varied industrial pursuits created a revolution in this. It is already a long time since the dyspeptic, narrow-chested, pale-faced, weak-eyed male became an object of interest by becoming a book-worm. A knowledge of Greek no longer condones a want of vigor and vivacity in the male, and we do not believe it is any more likely to in the female. Those who run any risk of health by pursuing advanced studies had best not trifle with the experiment.

The prophets of hygienic righteousness, as physicians have been termed, should throw the weight of their influence in favor of everything that improves the *physical* development of women. When they find the rate of growth is excessive, or accompanied by an imperfect development in weight, when the chest capacity is small, and the blood poor in hæmoglobin, they should prescribe more out-of-doors and a postponement of literary ambitions: more sunshine and fewer books. A good practical guide as to the physical condition in the rough is the relative increase of growth compared with the increase in weight. And Bowditch's tables in the eighth and tenth volumes of the Massachusetts Board of Health Reports are valuable as a standard of comparison.

## THERAPEUTICS JUDGED BY STATISTICS.

In a popular novel the hero, who was valet to a physician, was said to be able always to discover the secrets of his master's *clientèle* by consulting the prescription-book of the latter! If we knew the kinds and quantities of remedial agents used in a particular country during a series of years, we should have a tolerable general idea of the medical history of that country, for it is needless to say that the drugs of an age represent both the pathological tendencies and the therapeutical notions of that age. This, however, is not all, for statistical data of the kind indicated would bring vividly to view the popularity and decadence of remedies, as illustrated in innumerable instances; also the fact that medical fashions have continually changed, sometimes in accordance with the ill-based vagaries and hypotheses of the leaders, sometimes in correspondence with real advances in knowledge. Such tabulated statements as have been given by Lasèque and Regnault, in their elaborate monograph<sup>1</sup> (and we are not aware of any similar statistical inquiry ever having been made elsewhere), indicate therapeutic progress. The general drift of medical sentiment is manifested with clearness and certainty in the prescriptions of its leading representatives, and the great body of the profession slowly but surely come into line.

An example of this is seen in the almost universal adoption of the bromide medication, within ten years of the announcement of the special neurotic properties of this salt. In fact, it would be easy, as Lasèque remarks, to show that there has been an increased demand for the bromides in the exact chronological order of the appearance of recent popular treatises on these preparations and on epilepsy. In 1855 the total quantity of bromide of potassium furnished to the trade of Paris by the Pharmacie Centrale, which centralizes the preparation, purchase, and distribution of all medicines, without exception, employed in the hospitals of that city, was 3,200 kilogrammes. This figure was largely in excess of that of any previous year, and especially of 1850, for between the latter date and 1855 had appeared the special treatises of Rames and Huette on the physiological and therapeutie effects of bromide of potassium, and the value of Locock's discovery, who first experimented with bromide in epilepsy, in 1851, had become widely known through the medical journals. From 1855 to 1861 numberless experiments with the bromide in hospitals and in private practice, confirmatory of its utility in epilepsy, had been made, and by referring to Lasèque's table we find that the consumption of this salt had risen to the astonishing figure of 22,300 kilogrammes. As we follow the table down to 1875 we find proof of a constantly increasing demand, till the latter year gives the enormous consumption

<sup>1</sup> Archives Générales de Médecine, 1877. — *Études Médicales*, 1884. Tome I, p. 192.

of 730,910 kilogrammes. These figures bespeak, better than the most eloquent praises, the general success of a remedy which only by the satisfaction which its use has given could have so retained its hold on the profession and so grown in favor.

With regard to the decadence of general blood-letting, it is difficult to obtain exact figures. As is well known, this antiphlogistic practice was almost universal from the time of Hippocrates down to Bouillaud, who carried it to such excess, bleeding without stint, *coup sur coup*, in all inflammatory diseases. It is equally true that there are multitudes of physicians in active practice at the present day who have never seen a patient bled. Philippart, of Tournay, in his late thesis on "Blood-letting in Acute Diseases," gives the curious fact that the physicians of the hospitals attached to the Bureau Centrale, out of eight thousand consultations in 1867, ordered bleeding in only two cases, while in 1852, in a similar number of consultations, venesection was prescribed 1,259 times.

But the almost utter lapse of faith in these sanguineous spoliations is clearly exemplified in the table of Lasègue and Regnault showing the quantity of leeches employed in the hospitals of Paris from 1820 to 1875 and the sums expended therefor:—

Years.	Mean Annual Consumption.	Mean Annual Cost.
From 1820 to 1824	183,000	10,000 francs.
From 1824 to 1830	508,000	40,000 francs.
From 1830 to 1842	828,000	90,000 francs.
From 1842 to 1850	430,000	75,000 francs.
From 1850 to 1855	225,000	45,000 francs.
From 1855 to 1863	138,000	14,000 francs.
From 1863 to 1870	65,000	6,000 francs.
From 1870 to 1875	32,000	1,500 francs.

In the earlier years indicated in the above table the leech was employed more for an antiphlogistic and spoliative than for a derivative or revulsive effect,—the latter being, we hardly need say, almost the sole purpose for which leeches are ever prescribed at the present day,—nor was it an uncommon thing to order the application of twenty or thirty of these annelids over the inflamed lungs or peritonæum; hence, with the general abandonment of blood-letting, the demand for leeches has become very much restricted.

Coincidentally with the decline of the antiphlogistic treatment there has been an increased consumption of quinine and alcohol, and other agents of the tonic medication. The supplies of quinine and the cinchona barks furnished to the city hospitals have more than doubled within thirty years, as unerring figures show, and the quantities and cost of the various alcoholic preparations since 1855 have, as Lasègue observes, assumed colossal proportions. The table given by Lasègue and Regnault is too long to reproduce here, and we content ourselves by quoting the figure of 1,270 litres of alcohol for

1855 as contrasted with 37,578 for 1875; of 17,752 litres of red wine for 1855 as opposed to 163,762 for 1875; of 199 litres of rum for the former as opposed to 5,682 for the latter year. "It is," says Lasègue, "a fair indication of our therapeutical tendencies, this enormous increase in the consumption of alcohol, of brandy, and of wine in the treatment of diseases and in the hygienic care of the convalescent."

As for the iron preparations, the statistics above referred to show that usage has not much varied; sometimes one salt has the ascendancy, sometimes another. The manufacture and sale of ferruginous pills (Quevenne's iron, the protocarbonate, etc.) has increased; the iodide (syrup and pills) has more than quadrupled in demand, a fact which probably indicates growing confidence in the "resolvent" and "alterative" as well as blood-renovating properties of this martial salt. The perchloride still maintains its ancient high rank.

A notable increase in the employment of iodide of potassium was observed, but this may be due rather to the augmentation in the doses given the past twenty years than to the greater prevalence of syphilis.

Most of the mercurial preparations have remained stationary; the consumption of the bichloride has more than quadrupled since 1855; that of calomel varies per annum between thirty-five and fifty-five kilogrammes.

Chlorate of potassium has seemed to possess an exaggerated importance which its therapeutical properties certainly do not justify; the annual supply to the hospitals having attained a maximum figure of 502 kilogrammes, as contrasted with the figure of thirty-eight kilogrammes in 1855.

The consumption of opium and other anodynes has not much varied, while that of chloral has steadily increased since 1869, the year of its introduction. Ether maintains its superiority over chloroform as an anæsthetic in hospital use, almost in the ratio of two to one.

Pepsin, whose first appearance on the shelves of apothecaries scarcely dates back twenty-five years, has constantly risen in favor—whether because it possesses any great therapeutic virtue besides being innocuous, it is hard to say. Lasègue and Regnault give the startling figure of 38,375 kilogrammes for 1875, as contrasted with 200 kilogrammes for the year 1860. According to the French tables the mean annual delivery of subnitrate of bismuth to the hospitals for twenty years had not changed from 350 kilogrammes; that of tannin, catechu, and other astringents remaining also the same. The Paris population also consumes about the same quantities of purgatives of all kinds year after year, with a decidedly increased demand for mineral waters. As for tenifuge medicines the annual average figure before 1870 was 25,061; since 1870 it has been

40,336, a very marked increase: showing that the number of patients treated for tania has nearly doubled. Of the various anthelmintics the most in demand is pomegranate bark; the next in point of importance seems to be filix mas.

Under the influence of more enlightened views as to public sanitation and infectious disease, there has been an enormous increase in the annual consumption of antiseptics and disinfectants, and especially of phenic acid; the figure of one hundred kilogrammes for 1862 contrasting strangely with that of 221,925 for the year 1875.

## MEDICAL NOTES.

### BOSTON.

—There has been only one fresh case of smallpox reported in Boston. Vaccination is proceeding and the little "scare" is subsiding.

—The city government has finally, after much vacillation and some too quite absurd opposition, appropriated \$40,000 for the erection of a new building in connection with the City Hospital, for the isolation of contagious diseases. That amount of money, although only half the sum asked for, could not possibly do as much good to the citizens at large — no, not even in the hands of the "paving department."

### PHILADELPHIA.

—The trustees of Jefferson Medical College, at a meeting held April 27th, elected Dr. J. W. Holland to the chair of Medical Chemistry.

### NEW YORK.

—The widow of ex-Governor E. D. Morgan, who died recently, bequeathed the sum of \$135,000 in charities, of which the Woman's Hospital is to receive \$20,000, and the Home for Consumptives \$5,000.

—The Grand Jury has found indictments for manslaughter in the second degree against Charles Buddensick, the builder, and August Franck, the subcontractor, for their part in the Sixty-second Street disaster, by which Louis Walters, one of the workmen engaged in the construction of the row of new houses which fell April 13th, was killed. The coroner's jury in the case brought in a verdict that the responsibility for the death of Walters rests primarily upon Buddensick, and to a certain extent also upon Franck, for the reason that they caused to be used materials which they knew to be totally unfit to enter into the construction of any building whatever, in the erection of the houses referred to, the manner of which, in defiance of law, experience, and commonsense, called for the severest punishment the law could inflict. The jury also lay the responsibility of Walters's death in a great measure on the incompetent examiners, and state that they find culpable negligence and looseness of discipline and supervisory control that could have retained in

responsible positions servants capable of permitting the erection of buildings that shame all mechanical instincts. In conclusion, the jury urge the importance of securing, by prompt legislative action, the exercise of a rigid and intelligent control over all future construction of buildings, and advise a department of buildings under one responsible head, an appointee of the mayor, as the best means of securing for the citizens of New York good and sufficient building laws. In the meanwhile, the State Senate has passed a bill designed to prevent such disasters in the future, which was introduced some time since, and ought to have become a law long ago. This bill was sent to Albany with the approval of the Real Estate and the Mechanics' and Traders' Exchanges, the Builders' Association, and the City Building Department, and is very minute in its provisions relating to the thickness of walls, the solid character of foundations, and the use of good brick, sand, and mortar.

—The annual meeting of the Charity Organization Society was held April 14th, with the president, Dr. S. Oakley Vanderpoel, in the chair. The secretary's report showed that the names of 201 societies and churches are recorded in the society's books as having sent in the names of families or individuals who are objects of charity, and that 181,000 names of such families and persons are on file. The active work of the organization is accomplished by district committees and visiting officers, who become thoroughly acquainted with the condition and wants of the poor in the various portions of the city. The society has nine districts, embracing the region on the east side of town from Houston to Seventy-ninth Street, and on the west side from Houston to Twenty-third Street, under its charge, and employs 191 visitors. In the past year 9,311 families, representing 32,000 persons, have applied for help, and 208 were put in hospitals. Relief was secured 1,168 times from churches, hospitals, and individuals, and regular employment was obtained for 568 persons. The society has 55,000 families registered. Out of 1,152 begging cases, only 60 were found to be really needy. Addresses were made on this occasion by the Hon. Abram S. Hewitt, the Rev. Arthur Brooks, and the Rev. Edward Everett Hale, of Boston.

### BALTIMORE.

—Mr. J. Rendel Harris, associate professor of New Testament Greek and Paleography, at the Johns Hopkins University, seems to have found his field of instruction too restricted and to have fallen foul of the laboratory work of the biological department. As a consequence, Professor Harris's connection with the University has been severed. He announced that he "would rather resign all advantages of a connection with the University than compromise in the least degree his freedom of

speech," which is apparently to be interpreted that he does not care to teach New Testament Greek unless he can preach antivivisection. Mrs. Harris is said to be of the strictest sect of English antivivisectionists.

*Appropos* of the little tempest which disappeared almost as soon as it threatened to succeed this event, President Gilman makes the following statement in regard to the pursuit of biology at the University:

"The study of biology has received from the trustees the most careful consideration ever since the University was organized. In this institution painful experiments have never been performed for entertainment or to illustrate facts already ascertained. In such researches as are indispensable for the advancement of knowledge extreme care is taken, by the use of anesthetics, to render the subjects unconscious; or, when in rare instances this is not compatible with the successful accomplishment of the investigation, to reduce the pain inflicted to a minimum. Painful experiments are only permitted at the hands of thoroughly trained investigators and for the advancement of knowledge. Here and elsewhere, during the last ten years, such discoveries as to the nature, the causes, the prevention, and the cure of disease have been made through experiments on animals as have satisfied the authorities that the hope with which they founded a biological school in the University has been justified. I see no reason to think that they will change their deliberately and thoughtfully adopted course of conduct in regard to this matter.

"I am sorry that religious questions should be by any one brought into this discussion, for, important as they are, they are not relevant. But, as attention has publicly been called to them, it may be well to reiterate words which have repeatedly been printed in our official documents, and are more significant than any utterance which might be evoked at the moment," etc. etc.

### Correspondence.

#### MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

NEW ORLEANS, April 30, 1885.

*Mr. Editor,*—Here we are in the city of New Orleans on a bright, beautiful day, the thermometer at eighty-five degrees, and everything in full foliage and blossom. There is a pleasant air stirring, and the American Medical Association has just completed its third day of general session in harmony and general good feeling. The attendance at the meeting is large, but of course not comparable to the usual attendance in our more northern cities. The number registered has been over six hundred. The meeting of the American Surgical Association at Washington led several of its members to go directly from that place to this city, especially as on one of the routes, by the Shenandoah Valley, there were drawing-room cars provided without charge. This route is full of beautiful scenery, but here, as elsewhere, the accommodations for meals are very inferior, and the traveler does well who takes his well-filled lunch-basket with him. The

addition of a buffet-car is very agreeable, only it does not stay long enough with the train. After the experience of the heat of the week preceding the meeting, which was so general in the Atlantic cities, serious apprehensions were felt as to the temperature here, but the reality proved an agreeable surprise. New Orleans has had a week of heavy rains, and therefore was well washed out, muddy to be sure, but comparatively clean, and the magnolias, honeysuckles, roses, and other plants of delightful odor were all so far advanced as to mask the smells of the street-gutters quite satisfactorily. The nights are cool and pleasant and some slight wrap is useful.

The system of registration adopted here is an admirable feature of the meeting. The general meeting being in Tulane Hall, the Sections and registration were held in Tulane University, an adjoining building with a connecting-bridge between the two. There were four separate tables, each provided with two officials, these tables corresponding with four divisions of the alphabet; here the fee was received and the registration made; the delegate was then told to call at the special post-office in about an hour and all his credentials would be ready for him. In this way all crowding, pushing, and confusion were avoided. The post-office had its windows on a large roomy porch, so that the moment the fee was paid, and the credential turned in, there was no more anxiety, and the delegate was free to fill his pockets with advertising circulars, taste malt extracts, or attend to his proper business without delay. The place of meeting for the general sessions is large and capacious, perfectly plain and simple, and well adapted to the purpose.

The application for registration had the now usual form of subscription to the Code of Ethics, and, in addition, a blank for recording the temporary residence of the member while in the city.

Massachusetts is represented by a few delegates; Drs. A. D. Sinclair, J. R. Chadwick, G. M. Garland, H. O. Marey, with J. L. Williams, J. C. Irish, of Lowell, and Dr. A. H. Wilson, being present. There are very few New York men here, and Philadelphia has not sent many outside of the officers. Washington has only three representatives unless the Army, Navy, and Marine-Hospital men may be counted with them; Drs. Billings, Peck, and Hamilton representing these services. Dr. Gunn, of Chicago, is a prominent figure, and the familiar faces of many of the constant attendants are seen as usual, but the great bulk of the attendance is from the South and Southwest. The general feeling is very cordial. The only disturbing element to the general harmony was the severe strictures made by some members upon the action taken in forming the programme for the International Medical Congress which meets in Washington in 1877. Dr. Billings, on the first day in general session, made a statement of what had been done in this direction, and the subject was taken up for consideration on the second day, when Dr. Shoemaker, of Philadelphia, made some positive remarks, criticizing the action taken as exceeding the authority given by the Association to its delegates to Copenhagen, as ignoring certain members, and as appointing New Code men to representation. Dr. Billings, in reply to this, spoke, as he said, simply to give the manner in which the committee had acted, and why they had so acted, without thinking it necessary to make a defence or give an excuse. He did not think that was necessary, but emphatically denied the imputation of any collusion or bargaining. He considered the fact of being named as connected with the programme of arrangements as of much less importance than the prominence which would be given to the men, committee or no committee, who would bring new and valuable matter before the Congress itself. The members of committees in the Copenhagen Congress were already forgotten in most

instances, but the men who read valuable papers at that Congress still stood out in strong contrast. The idea was to get the work in hand as soon as possible, with the intention of enlarging the committees in every direction as soon as practicable. This discussion led to resolutions from Dr. Daniels, of Texas, to ignore the work done, and appoint a new committee to arrange for the Congress. Dr. Keller, of Arkansas, however, presented a resolution, which was adopted, to appoint representatives from each State and Territory, and the Army, Navy, and Marine-Hospital service, to be added to the original seven, with power to review, alter, and amend the presented report as they may see fit. Thus ended, for the present, an awkward subject to handle.

The Nominating Committee presented a report, which was adopted in full, making Dr. Brodie, of Detroit, the President for 1886, and St. Louis the next place of meeting. In regard to the latter there was some question as to whether Washington was not the place fixed upon for meeting each alternate year by resolution, but the resolution of last year was construed to mean in case no invitation came from other sections of the country. Dr. N. S. Davis has again been elected as editor of the *Journal*, and agrees to continue his services as such. In his remarks upon this subject Dr. Davis recognized the criticisms which have been made regarding the *Journal*, and the justice of some of them provided the Association had the means of making it what it should be, but to husband the resources of the Association he considered as of the first importance,

and he had been subjected to much embarrassment in this respect, while now the increase in membership and available funds had been very great.

The entertainments have been very cordial and interesting. Dr. and Mrs. Richardson and Mr. and Mrs. Cartwright Eustis have thrown their houses open to the delegates by giving evening receptions, and the New Orleans Jockey Club has given a reception with music on its beautiful grounds, which are some distance out from the centre of the city and represent admirably what can be done with the luxuriant garden growths of this section. This reception being very general the grounds were filled with agreeable people. Thursday (to-night) the profession gives a ball and promenade concert, which closes the list.

I have said nothing of the Exposition, but it forms an important feature of the meeting; it is very accessible, and, while it has not the features of architecture and art which characterized our Centennial in Philadelphia, as an educational exhibit it is wonderfully good, and is especially interesting in the exhibit of the Southern States. The medical features form no unimportant part, and our Government display of hospital models, hospital tents, appliances, ambulances, etc., is very complete. Mexico has also some very excellent surgical instruments and interesting pathological specimens.

The meetings of the Sections, I presume, you will have in full and detailed accounts. They were well attended, and the papers appointed to be read before them were very well selected.

## REPORTED MORTALITY FOR THE WEEK ENDING APRIL 25, 1885.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from				
				Infectious Diseases.	Lung Diseases.	Diphtheria and Croup.	Scarlet Fever.	Measles.

Deaths reported 2,667; under five years of age 934; principal infectious diseases (smallpox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrheal diseases) 371, lung diseases 489, consumption 934, diphtheria and croup 109, scarlet fever 63, measles 49, diarrheal diseases 46, typhoid fever 27, malarial fevers 26, erysipelas 17, cerebro-spinal meningitis 14, whooping-cough 12, puerperal fever eight. From diarrheal diseases, New York 14, Brooklyn seven, Boston five, Philadelphia and New Orleans four each, Cincinnati and New Bedford each three, Baltimore two, District of Columbia, Nashville, and Salem one each. From typhoid fever, Philadelphia seven, New York and Boston four each, Brooklyn three, Cincinnati and Holyoke two each, New Orleans, District of Columbia, Charleston, Lawrence, and Salem one each. From malarial fevers, New York 11, Baltimore four, Brooklyn and New Orleans three each, District of Columbia and Charleston two each, Philadelphia one. From erysipelas, Philadelphia five, New York four, Brooklyn three, Baltimore two, Boston, Cincinnati, and District of Columbia one each. From cerebro-spinal meningitis, Philadelphia four, Springfield three, New York and Fall River two each, Baltimore and Cincinnati one each.

Cases reported in Boston: smallpox two, measles 96, scarlet fever 27, diphtheria 23, and typhoid fever seven.

In 126 cities and towns of Massachusetts, with an estimated population of 1,462,792 (estimated population of the State 1,355,104), the total death-rate for the week was 19.73, against 20.15 and 21.77 for the two preceding weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,906,446, for the week ending April 11th the death-rate was 25.9. Deaths reported 4,271; infants under one year of age 967; acute diseases of the respiratory organs (London) 512, measles 164, whooping-cough 127, diarrhoea 49, scarlet fever 31, fever 35, diphtheria 29, smallpox (London 36, Sunderland two, Manchester and Leeds one each) 40. The death-rates ranged from 20.0 in Brighton to 41.9 in Newcastle-on-Tyne; Birmingham 25.7; Blackburn 25.5; Bradford 25.1; Leeds 20.5; Leicester 21.5; Liverpool 24.7; London 23.8; Manchester 26.9; Nottingham 26.7; Sheffield 23.6. In Edinburgh 18.5; Glasgow 29.1; Dublin 32.2.

For the week ending April 11th in the Swiss towns there were 44 deaths from consumption, lung diseases 39, diarrheal diseases 12, diphtheria and croup eight, erysipelas three, puerperal fever four, measles two, whooping-cough two, smallpox, scarlet fever, and typhoid fever one each.

The death-rates were: at Geneva 14.2; Zurich 7.8; Basle 14.4; Berne 32.8.

The meteorological record for the week ending April 25th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending Saturday, Apr. 25, 1885.	Barometer.				Thermometer.				Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall. Duration, Hrs. & Min. Amount in Inches.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM APRIL 25, 1885, TO MAY 1, 1885.

BYRNE, CHARLES C., major and surgeon. Assigned to duty as attending surgeon at the Soldier's Home, D. C., to take effect May 15, 1885.

DE WITT, CALVIN, captain and assistant surgeon. Upon being relieved by Surgeon Byrne, ordered to report to the Surgeon-General of the Army. S. O. 91, A. G. O., April 25, 1885.

TORNEY, GEORGE H., captain and assistant surgeon, United States Army. Assigned to duty at Fort Monroe, Va. S. O. 87, Department of the East, April 25, 1885.

CHAMFORD, L. W., captain and assistant surgeon. Assigned to duty as post surgeon, Fort Bridger, Wyoming Territory.

BORDEN, WILLIAM C., first lieutenant and assistant surgeon. Ordered for duty at Fort Douglas, Utah Territory. S. O. 33, Department of the Platte, April 22, 1885.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE WEEK ENDED APRIL 25, 1885.

SAMUELLE, H. W., surgeon. When relieved, to proceed to Detroit, Mich., and assume charge of the service. April 23, 1885.

FRIGHARI, F. M., passed assistant surgeon. To assume charge of Cape Charles Quarantine Station. April 23, 1885.

WILLIAMS, L. L., assistant surgeon. When relieved, to proceed to Norfolk, Va., for temporary duty. April 23, 1885.

#### SOCIETY NOTICES.

THE NORFOLK DISTRICT MEDICAL SOCIETY will hold its annual meeting at Rockland Hall, 2343 Washington Street, Roxbury, on Tuesday, May 12, 1885, at 2 o'clock p.m. The Board of Censors will meet at 1 o'clock. Communications: "Cholera," by Harold C. Ernst, M.D., Jamaica Plain.

GEORGE D. TOWNSHIP, M.D., Secretary.  
SUFFOLK DISTRICT MEDICAL SOCIETY.—The Section for Clinical Medicine, Pathology, and Hygiene will meet at 19 Boylston Place, on Wednesday, May 13, at 7.45 o'clock. Papers: Dr. Vincent Y. Bowditch, "Description of Dr. Herbert E. Williams's Pneumatic Differentiator for the Treatment of Pulmonary Diseases." Dr. George B. Shattuck, "Results of the Use of Antipyrin at the Boston City Hospital."

ALBERT N. BLODGETT, M.D., Secretary.  
NEW YORK STATE MEDICAL ASSOCIATION. FIFTH DISTRICT BRANCH, BROOKLYN. SCIENTIFIC MEETING.—The second special meeting of the Fifth District Branch will be held at the Morgan House, Poughkeepsie, at 2.30 p.m., on Tuesday, May 19, 1885. The following papers will be read: "Three Cases of Ligation of the External Carotid; in two both vessels were tied simultaneously," by J. D. Bryant, M.D. "Diphtheria and its Treatment by Calomel," by S. J. Murray, M.D. "Hypertrophy of the Prostate Gland," by J. G. Porteus, M.D. "Treatment of Cerebral Hemorrhage and Embolism by the Internal Use of Carbamate of Ammonia," by R. C. van Wyck, M.D. "Report of a Case of Rheumatic Metastasis to the Brain ending fatally," by C. S. Wood, M.D.

J. C. HUTCHISON, M.D., President.  
E. H. SQUIBB, M.D., Secretary.

#### APPOINTMENT.

SUPERINTENDENT OF THE BOSTON CITY HOSPITAL.—Dr. G. H. M. Rowe has been re-elected Superintendent of the Boston City Hospital.

## Original Articles.

A CASE OF PSEUDO-MEMBRANOUS  
ENTERITIS.<sup>1</sup>

BY O. W. DOE, M.D.

A FEW months since, I showed to this Society a collection of false membrane passed per rectum, but as the patient had at that time just come under my care, I was unable to give any detailed history of the case. It proved to be another similar to those so interestingly reported by Dr. Goss, and published in the records of this Society, vol. viii. page 211, of the appendix, and supplemented by three cases reported by Dr. Boardman.

In the discussion which followed, Dr. Boardman was inclined to the belief that the cause of this disease was to be referred primarily to some disorder of the nervous system, and the intestinal disturbance was a secondary affection. Da Costa, in an article on this subject published in 1871, supports this view and remarks that all of the seven cases reported by him occurred in very nervous and hysterical patients. Habershon, physician to Guy's Hospital, thinks the nervous manifestation a symptom, rather than a cause, of the disease.

As the theories regarding the nature and cause of this very rare affection are so indefinite, I report the following case rather fully, hoping it may suggest to some of the members present a plausible explanation of this disease.

Mrs. G., aged forty-four, consulted me professionally April 19, 1884, and gave the following history: Her mother died of consumption; her father of diabetes, and one uncle of cancer. From her earliest remembrance she suffered from facial neuralgia, and at times from pain and distention at the epigastrium.

At fifteen she had scarlet fever; at eighteen fell from a carriage and fractured the patella, and as a result of the confinement necessitated by this accident, constipation and hemorrhoids followed. During this time she had pneumonia and indefinite cardiac trouble. At twenty, had typhoid fever, and for months afterward distress after eating. At twenty-four, again had typhoid, and went nineteen days without a movement of the bowels; at twenty-six had again a slow typhoid; was married the same year and became pregnant in two months. For a year after her confinement she suffered from pain at the rectum, and since then has had no expulsive power when at stool unless the dejections are loose; if constipated is always obliged to take an enema. At thirty-one, she had another attack of typhoid which lasted five weeks and terminated with numerous black dejections resembling tar. At thirty-three had varioloid, followed by slow fever which lasted several weeks, and during this time had frequent purulent dejections, and there was almost constant abdominal distention. Since that time she has never been entirely free from distress and pain at the epigastrium. At thirty-seven, seven years ago, after overworking at dressmaking, she began to lose strength and to suffer with in-

creased distress at the stomach; three months later was suddenly seized with intense pain referred to a point an inch above umbilicus and an inch outside of the median line; this was followed by marked tenderness and distress after taking food. During this illness, which confined her to bed for several months, and which the physicians called nervous prostration, the chief symptoms were gastric disturbance attended with obstinate constipation and the passage from the bowels of pieces of membrane resembling skin, three to four inches in length. About that time she first began to notice a "bunch in the stomach," which was the seat of severe pain whenever cathartics were used, and consequently she depended wholly upon enemata. Whenever she used large injections of warm water, there seemed to be an increased amount of the membranous pieces pass away. Any kind of food caused distress and accumulation of gas in the stomach, but no vomiting; she was greatly depressed and uncontrollably nervous. At forty she had a recurrence of the membranous dejections with an attack of severe gastric disturbance and hysterical manifestations. After five weeks she noticed a pulsation in the region of the stomach which the physicians thought was a tumor, the pulsations being so very strong as to visibly move the bedclothes. This came on after wearing for a week a pessary for retroversion. Her eyesight became so dim that she could not recognize a person across the room; there was obstinate constipation with distention of the abdomen. One year later she had another severe attack attended with diarrhea, coming on after having taken a large dose of magnesia, but continued only a few days.

The present attack began in January of 1884, with chills and fever, preceded by weeks of nervous depression and pain in the head and along the spine. The same gastric disturbance, as previously mentioned, came on with constipation. There were chilly sensations followed by fever daily and attended with considerable thirst; sleep was disturbed; appetite remained tolerably good.

Soon after the beginning of this present attack she noticed a reappearance of the strings of membrane in her dejections, which have continued since, and ten days ago one piece was passed which measured twenty-seven inches in length, yellowish-white in appearance, tough, and having ragged edges; some of the pieces were an inch in width. There was generally marked tenderness over the whole abdomen after passing these strings and shreds of membrane. The gastric symptoms have continued up to the present time, there being more or less nausea, pain in the stomach, and a "heaving" in that region which is increased by cough or the least exertion. Food always causes distress and an excessive formation of gas. The bowels, a week before I first saw her, had been moved naturally about three times daily, there having been previously habitual constipation requiring the frequent use of injections. The discharges had been of a very sickening odor, containing hard scybala masses and but very little mucus. The appetite had failed and she had lost strength rapidly. She had noticed that whenever she had these attacks

<sup>1</sup> Read before the Boston Society for Medical Improvement, April 27, 1885.

she always took the dorsal position in bed with the knees drawn up.

The condition in which I found her at my first visit, April 19th, was one of general exhaustion. She was anemic; her countenance was sallow, her flesh flabby, appetite very poor, tongue furred, and there was inability to sit up for any length of time. The abdomen was soft, not distended, and not particularly sensitive on pressure excepting over the descending colon and just above and to the right of the umbilicus. At this point there was a hard mass detected, the size of an English walnut, without pulsation and without thrill. It seemed to be slightly movable on very full inspiration. Pulse and temperature were normal; examination of urine showed nothing abnormal. Tonics were advised. Quinine and iron and an injection of a quart of warm water was ordered to be taken daily, the bowels being at this time quite constipated.

April 29th. Injections brought away fully a pint of very hard scybulous masses, a large amount of mucus mixed with black tarlike substance of very bad odor.

April 30th. Felt very feverish after the dejections of yesterday; abdomen sensitive on pressure throughout; complains of palpitation; left arm is very weak; is very hysterical; has had three dejections containing a large amount of mucus. Carlsbad salts ordered to be taken three times a week, and large injections to be given on alternate days. Murdock's food advised to be taken in wine every two hours.

The salts produced free dejections and for the first time without mucus. On May 11th there was noticed a little blood in the dejections, and she felt very much weaker. Eyesight would become dim upon raising her head from the pillow; continuous pain at the stomach; increased distress after taking any nourishment; abdominal distention from gas; rush of blood to the head; ringing in the ears and gasping respiration. The salts were omitted. Milk and Seltzer water in equal part, were ordered to be taken in small quantities, and Hunyadi water as required. On the 18th she showed some improvement in strength and the bowels had moved every day, the discharges consisting of small scybala without membrane.

21st. Was able to sit up and walk about a little.

22d. Eight tablespoonfuls of Hunyadi produced seven dejections, containing considerable mucus of intensely foul odor, very black, and showing small black particles like coaldust adhering to the vessel.

25th. Dejections still black; stomach irritable; recurrence of pain in back and limbs.

28th. Has sat up a portion of each day, but walking about the room causes a burning and tired feeling in the abdomen and produces considerable meteorism.

June 1st. Walked a short distance out of doors. No change in the character of dejections, but containing less mucus. Hunyadi water produces two or three movements daily.

5th. Feels very much exhausted; return of distress after eating; pain over whole abdomen, which is tympanitic on percussion.

13th. Since the 7th has had one discharge daily,

black in color, resembling tar, containing a little mucus and coaldust particles, and of the foulest odor. The discharges produce a scalding sensation at the anus and foam when water is added to them. The patient feels stronger and able to sit up half the day. Examination of the abdomen fails to detect the hard mass above the umbilicus, previously referred to.

19th. Gaining strength rapidly; four dejections to-day after taking Hunyadi, one of them consisting entirely of mucus.

24th. Decided improvement in every way; very little pain; bowels moved yesterday and to-day without assistance, and the discharges have a more natural appearance; the foul odor and black color have disappeared; food causes but little distress.

28th. The discharge to-day has been the most natural for the past three months. No Hunyadi required.

July 5th. Takes solid food without distress. Dejections natural in appearance, is able to be out of doors, and assists at her work about the house.

Since last July, until two weeks ago, the patient has remained comparatively well, but has now become quite exhausted from attendance on a sick daughter, and the former gastric symptoms have returned, though mild, and there is a reappearance of the small membranous shreds in the discharges. On examination of the abdomen two days ago I again detected the hard mass, though very small, just above and outside the umbilicus.

Leube, in his article on "Diseases of the stomach and intestines," in *Ziemssen*, refers to this form of enteritis as one very rarely seen, and usually only in hysterical patients. The symptoms, as described by him, were all prominent in the case I have reported, and the pulsation and "beating," so often complained of by my patient, *Da Costa* mentions as one of the most frequent and annoying symptoms. In my case this seemed to be referred to the localized hard mass above the umbilicus.

The history of the whole case bears out the probability that the abdominal symptoms were a secondary result of some primary nervous derangement. Dating far back, *Henri Herchard* reports a case similar to mine preceded by constipation, dependent upon some obscure nervous affection.

*Habershon* describes all the symptoms I have mentioned and ascribes them to a chronic catarrh of the colon, and designates the disease as one of chronic mucro-colitis. He advances no theory regarding the cause of the disease. In a post-mortem examination in one case there was found to be a gray zone surrounding the follicular glands, thickening of the mucous membrane, and weakness of the muscular coats of the intestines. And, in another case, there was found imbedded in the folds of the mucous membrane of the colon and firmly retained there, scybala of considerable size. It has occurred to me that perhaps that fact might explain the doubtful tumor noticed at the epigastrium, in the region of the transverse colon, and lying over and upon the abdominal aorta where the pulsation was so distinctly felt, and might not this retained scybulous mass act as the exciting cause of the enteritis? Its disappearance, after numerous dejections produced by Hunyadi, coincident with a

mitigation of the abdominal symptoms and diminution in the amount of membrane, and a reappearance of the tumor and return of the membrane during the past week, seems to make this theory plausible.

## TWO CASES OF DANGEROUS HÆMORRHAGE FROM RUPTURE OF THE VAGINA DURING FIRST COÏTUS.

BY PAUL F. MUNDÉ, M.D., OF NEW YORK.

DR. CHADWICK's case of "Rupture of the Vagina during Coitus," reported in the issue of this journal for April 30th, recalls to my mind two cases observed by me and reported to the New York Obstetrical Society at the time, in both of which very severe hæmorrhage occurred from a rent in the left vaginal wall, in the first case the fissure being an extension of the physiological laceration of the hymen. The comparative rarity of this accident (vaginal rupture and bleeding from deep fissures of the hymen is not so uncommon), especially in young healthy women with properly shaped and normally elastic vaginae, leads me to add a brief report of my cases to those already published.

CASE I. In October, 1881, I was called early in the morning to a hotel in this city to see a lady who had been married on the previous day. I found her in a state of collapse, pale, with occasional momentary loss of consciousness, all due to a violent hæmorrhage immediately following the first coition. The husband, a physician himself, had vainly tried to arrest the hæmorrhage by compression and persulphate of iron. Inspection showed blood trickling from the vaginal orifice and a slight rent of the hymen at the left anterior border, which, however, did not bleed; digital examination revealed a vagina distended with coagula, thus indicating that the blood flowed inward, as though from an internal wound. Placing the patient on the left side, I introduced Sims's speculum, cleared the vagina thoroughly of all coagula, and then at once saw the blood spurting from a deep fissure about an inch long, which extended inward from the nick in the hymen to the left and parallel with the urethra. Tight tamponing of the vagina with disks of alum-cotton, carried down to the very vulva, arrested the bleeding at once and permanently, and no further trouble was experienced. Here really the rent was intravaginal, its starting-point merely being the hymen.

CASE II. April 16, 1883, I was called, in the evening, to see a lady twenty-two years of age, married the day before. The messenger said she was bleeding, and I suspected a similar injury to that in the previous case. I found a waxy-looking, evidently very feeble patient, who stated that coitus had been performed but once, toward morning, had been rather painful, that she then went to sleep, and was awakened some hours later by feeling wet about the genitals, and found herself lying in a pool of blood. A physician was sent for who gave ergot, but made no examination. The patient continued to ooze, and another physician was sent for, who ordered ice to be applied over the abdomen, but also made no examination. The hæmorrhage continuing, he

sent for me. I examined her by gaslight, and could detect no bleeding spot on the hymen. The examining finger found the vagina full of coagula. Through Sims's speculum the vagina was thoroughly cleansed, and a deep rent fully two and a half inches in length and half an inch in depth was at once seen in the left vaginal wall, extending from about an inch above the hymen nearly to the cul-de-sac. The edges of the rent were ragged, and its base bruised and torn. A firm tamponade with alum-cotton disks effectually controlled the bleeding, and when the patient called at my office, a week later, the wound was in a fair way toward closure.

In neither of these cases did there seem to be a disproportion of the relative organs, nor could I learn that any unusual violence had been used. The vaginae were apparently perfectly healthy, both ladies being young and of good constitution.

In the second case of Zeiss, quoted by Dr. Chadwick, the recent confinement of the woman and the adhesion of the cervix to the lacerated side of the vagina would readily account for the friability of the tissues, as would also the senile atrophy of the vagina in Dr. Chadwick's own case. I recollect reading a similar case in a Canada medical journal a few years ago, where a sailor had been away from home for nine years, and on first coition with his wife on his return ruptured her vaginal vault to such an extent that she had to be taken to the hospital (in Montreal, I believe), and came near dying. She had not as yet, if I remember correctly, reached the menopause.

It is strange that two such accidents should have been produced by sailors, whose reputation for abstinence, when away from home, is not of the best.

The treatment must obviously consist in the tamponade, repeated as long as danger of recurrence exists, or, if the rent is external, where a vaginal tampon cannot well touch it, the deep suture.

## POISONING FROM SARSAPARILLA (?) SODA.

BY CHARLES W. GILLOTT, M.D., OF LYNN, MASS.

THE following cases have the merit of novelty and indicate how the most ardent temperance man may become a victim to strong drink in the guise of "blood-purifying" sarsaparilla.

Two men of exceptionally vigorous health called upon a druggist at 9 p.m. for a glass of sarsaparilla sodawater, with which they were provided, accompanied by an assurance of its great medicinal value. In a few minutes Mr. P. began to complain of nausea, and for four hours after he vomited almost incessantly, the vomitus emitting such a pungent odor of sassafras as to pervade the whole house. When visited at ten o'clock he was in a state of semi-collapse with rapid and feeble pulse and cold, clammy skin. He complained of intense paroxysmal pain in the stomach, and vomited, at short intervals, a little dark liquid with a pungent sassafras odor. Although responding readily to questions, he complained that he felt as though asleep. By the aid of warmth and stimulants he rallied in a short time, and, although much prostrated by the attack, he returned to his office in a few days.

Mr. V. made no complaint for half an hour, when he was seized with severe cramps and an intense burning sensation in the bowels. He had no nausea, in spite of copious draughts of warm ginger-water taken as an emetic. He was very dull and drowsy and staggered like one intoxicated. Violent purging set in soon, and for three hours he rolled about the floor in agony; the discharges, which passed from him involuntarily every five or ten minutes, were watery and emitted an intense odor of checkerberry. In four hours he became easy, and, although still weak, was able to return to business in two days.

The symptoms in both cases were indicative of local gastro-intestinal irritation and general depression, the poison making itself felt in the stomach immediately in the one case, and in the intestine, after half an hour's interval, in the other. A visit to the druggist's elicited an explanation of the accident. It appears that the "sarsaparilla" syrup was made by the following formula:—

Oil of Sassafras	}	. . . . . 5i
Oil of Checkerberry		
Simple Syrup		. . . . . O iv

The volatile oils were mixed with an equal quantity of alcohol and then diffused in the syrup by shaking. The receptacle in the fountain was rectangular with a small base, and held two quarts, the faucet for drawing it entering at the extreme bottom of the can. Owing to defective mixing the oils gradually rose to the surface, and the last few glasses drawn contained nearly all the oils in the can. The clerk recollected refilling the can just after supplying our patients, so that they had the quantity of oil that had for two days been accumulating on the surface of the syrup. Mr. P. had the last glass, and this may account for the greater severity of his symptoms. These cases were not very serious, but their publication may happily serve as a warning to the economical druggist and the thirsty public.

## REPORT ON DISEASES OF CHILDREN.

By T. M. RITCHIE, M.D.

### TYPHOID FEVER IN INFANCY AND CHILDHOOD.

Dr. JULES SIMON publishes an elaborate article on this subject, in his "Conférences Thérapeutiques et Cliniques sur les Maladies des Enfants," tome ii., in which he makes the following distinctions between the typhoid of children and adults.

The pathology differs in some respects, the occurrence of ulcerations being comparatively rare in the young subject, a fact which he explains by the cellular infiltration not being massed together as in adults, but disseminated.

The younger the patient the rarer it is to have ulceration. Intestinal perforation and hemorrhages are both rare in children, and sudden death scarcely ever occurs. The liver is frequently found enlarged; the spleen is often not hypertrophied, and when there is an increase in its size this increase is notably difficult to detect during life.

The pathological lesions are apt to be abortive in type. Bronchopneumonia is quite a common com-

plication, and pulmonary and cerebral congestions are more prominent than in the adult.

Sometimes, after showing decided typhoid symptoms for seven or eight days, complete cessation of all signs of disease takes place and complete recovery. Where the differential diagnosis is uncertain early in the disease, it definitely declares itself in about eight days. During the first week the symptoms may be decidedly cerebro-spinal, and constipation and vomiting are so commonly met with during this period as to make the diagnosis often very difficult.

Typhoid fever in childhood is most common between the eighth and fourteenth year; it is rare under five years and quite exceptional under two, but may occur at any age. The author, in speaking of the treatment, states that the cold bath should be avoided as dangerous in comparison with its use in adults.

### TYPHOID FEVER IN AN INFANT NINE DAYS OLD.<sup>1</sup>

Ignatieff reports the case of an infant who on the sixth day of life began to be affected with frequent and offensive evacuations, the temperature also undergoing moderate elevation. Subsequently there were cyanosis and bloody evacuations, and on the third day of his illness the infant died. The autopsy showed the weight to be 3,400 grammes; skin slightly jaundiced; umbilicus normal; the brain and its membranes congested; the lower lobes of the lungs hypostatic, the upper ones anemic; the right side of the heart was dilated; the liver was enlarged, congested, and brittle; the spleen was enormously enlarged, congested, and firm, with its malpighian bodies swollen; the contents of the intestine were thin, and in the large intestine rather bloody; the mucous membrane of the intestinal canal was swollen and ecchymotic; the large intestine presented swelling and ulceration of the follicles; in the lowest portion of the ileum there were swelling and ulceration of Peyer's patches; the solitary follicles were also swollen and covered with necrotic tissue but not ulcerated; the mesenteric glands were swollen and hyperemic; the kidneys anemic; the umbilical vessels were obliterated.

The author concludes that the intestinal trouble could be regarded as nothing else but typhoid in character. This is the seventh recorded case of typhoid in the newborn infant.

Unfortunately nothing could be ascertained regarding the etiology of the disease, but the probabilities pointed strongly toward uterine infection.

### ALBUMINURIA OF THE NEWBORN.<sup>2</sup>

Ribbert, as a result of his investigations on the embryos of animals of different sizes and species, has come to the conclusion that a decided transudation of albumen passes through the glomeruli in the kidney of the embryo from the undeveloped condition of the glomeruli, and states that albumen is frequently found in the urine of the fœtus. The albumen which is at times found in the first urine which is passed after birth Ribbert considers to result from a continuation of the fetal condition.

<sup>1</sup> Jahrb. für Kinderheilk., B. xxi. H. 1. Archives of Pediatrics, December 15, 1884.

<sup>2</sup> Fortschritte der Medicin, February 15, 1885.

The more important albuminuria of the early days of infancy cannot be exclusively explained in this way, but probably is caused by the excessive metabolism which occurs in infancy.

#### ACUTE AMAUROSIS IN SCARLATINAL NEPHRITIS.<sup>3</sup>

A paper concerning amaurosis in a case of scarlet fever was read by Dr. Bechen, and discussed by others, in the Society for Internal Medicine, at Berlin, January 7, 1884. Inflammation of the shoulder-joint began in the second week of the disease, albuminuria and febrile phenomena in the fourth week, and violent headache with complete blindness upon the thirty-seventh day. Two hours after this accident an attack of vomiting ensued, and was followed by unconsciousness and general clonic spasms. After twelve hours unconsciousness passed away, and with it ability to distinguish light from darkness returned. After eight days the sight was normal again. The author thinks in almost all cases of scarlatinal nephritis uremia occurs when oedema disappears. His supposition is that acute oedema first invades the brain, and that the transfused serum has its toxic effect secondarily. In the course of the discussion Litten remarked that in almost all cases of coincident scarlatinal uremia and amaurosis there is no perceptible change in the retina, no congestion of the papillae are evident, there is no increase of intracranial pressure, and no intense oedema of the brain. The consideration of the reaction of the pupils was thought to be an important point in making a prognosis. Haltdammer gave as his opinion that from the reaction of the pupils it might be decided that the seat of the amaurosis was beyond the reflex centre.

Baginsky thought that there were cases in which amblyopia was found as a complication, and not amaurosis. He had found in the urine in cases of acute nephritis substances which belong to the group of guanin and xanthin, and the toxic effects are probably attributable to such substances. Leyden remarked that oedema of the brain is certainly associated with symptoms of uremia, and that the intoxication might be due to the holding back of certain necessary chemical elements. Lustig called attention to the fact that intoxication and amaurosis might follow the use of various substances, as quinine, nicotine, morphia, chloral, alcohol, and salicyl.

#### TRANSITORY HEMIPLEGIA, APPARENTLY DUE TO LUMBRICI.<sup>4</sup>

Girard reports the case of a girl four years of age, of nervous temperament and delicate constitution. Her mother was of hysterical temperament, and her father had syphilis five years before his marriage. There were no evidences of hereditary syphilis, no rachitis, no scrofula, and no cardiac difficulty. During dentition there had been several attacks of eclampsia and some abdominal trouble (not specified). The child was suddenly attacked with clonic convulsions, which were limited to the face and to the upper and lower extremities of the right side; they lasted about an hour, were accompanied with momentary loss of consciousness, and

were followed by complete motor paralysis of the right side. Intelligence remained, though it was somewhat blunted, and deglutition was unimpaired. The reflexes were equal on both sides; there was no disturbance of sensibility, and the pupils were equal, immobile, and dilated. Calomel was given empirically in consideration of the syphilitic antecedents of the father. The day following the paralysis the child was able to walk, and was bright and smiling, having expelled, during the night, about thirty lumbrici. The hemiplegia had completely disappeared and did not return.

#### TUBERCULAR MENINGITIS IN INFANCY.<sup>5</sup>

Medin, in a report of the General Children's Hospital, in Stockholm, from the year 1842 to 1881, states that the whole number of deaths was 5,110; of these 431 died of tuberculosis, but of these there were only 44 cases of decided tubercular meningitis (0.8 per cent. of all the deaths, 10.2 per cent. of the tuberculous cases).

Tuberculosis of the meninges without inflammation was also found in 23 cases, so that the whole number of cases of tuberculosis of the meninges was 67 (1.24 per cent. of all the deaths, 15.5 per cent. of tuberculous cases).

It was possible, also, that in some of the other cases there might have been tubercle of the meninges, but the symptoms during life not pointing toward the nervous system, the head was not opened. Decided tubercular meningitis was, therefore, of very rare occurrence among infants, simple meningitis without tubercle being six times as frequent. The greatest frequency of general tuberculosis was during the months of January and February, while tubercle of the meninges and tubercular meningitis occurred most frequently in May and July.

The symptoms of general tuberculosis were found to precede the outbreak of tubercular meningitis by two or three months. The deaths from tubercle of the meninges and tubercular meningitis were most frequent in the fourth, fifth, and sixth months, rarely in the first three months of life. General tuberculosis was rare in the first two months of life but very frequent in the third month. Of the 11 cases of tubercular meningitis 25 occurred in girls and 19 in boys; tubercle of the meninges without meningitis was found 12 times in boys and 11 in girls, and the disposition to general tuberculosis was found equal in both sexes. Out of the 67 cases where tubercle was found in the meninges there were only two where tubercle was not found in other organs. One of these cases occurred in a strong, well-nourished child, in whom no pathological changes were found beyond the tubercular meningitis; in the second case, also, with the exception of tubercular meningitis, no signs of disease could be discovered.

In one case tubercles were only found in the liver, in another only in the mesenteric glands, and in a third only in the bronchial glands.

In most of the cases of tubercle of the meninges without meningitis, there were no symptoms during life which pointed toward cerebral disease. In tubercular meningitis, on the contrary, cerebral

<sup>3</sup> Jahrb. für Kinderheilk., XLI. 4 Heft. Archives of Pediatrics, January, 1885.

<sup>4</sup> Revue Mensuelle des Maladies des Enfants. Archives of Pediatrics, February, 1885.

<sup>5</sup> Nord. Med. Ark. LV. 1881, No. 26. Jahrb. für Kinderheilk., XLI. B. 3 Heft.

symptoms were present, excepting in the cases where the tubercles involved a small territory, or where there was incomplete development of the disease.

The prodromal symptoms were, as a rule, absent, and the meningitis seemed to develop suddenly, even where perfectly healthy children were attacked. Somnolence was not so common in the tubercular cases as in the epidemic, but sopor and coma at the end of the disease were equally frequent. Hyperaesthesia was rare; sharp cries occurred in a few cases. Clonic spasms were frequent, tonic less so.

Strabismus was very common; irregular respiration occurred in four cases. Paralysis appeared in a number of cases; vomiting, as a prodromal symptom, occurred in three cases, after the development of meningitis in four cases; constipation was rare; diarrhoea more frequent. Sinking of the abdomen was not observed in any of the cases. Bulging of the fontanelle was frequently observed. The prognosis was as bad for the infant as for the child. The pathological conditions presented no differences from the older child. The length of the disease was from two to four days, in some cases from ten to twelve days, in only one case as long as a month, and in one case death took place in thirty hours.

#### THE TEMPERATURE IN TUBERCULAR MENINGITIS IN CHILDHOOD.<sup>6</sup>

Blasi has recorded the temperature in thirty-eight cases of tubercular meningitis in the Hospital Bambin Gesù, in Rome. Fever occurred in all the cases whether with or without complications, but the highest temperatures were where there were complications of pulmonary tuberculosis or pneumonia. Subnormal temperatures were only found in collapse toward the end of the disease; there was usually an evening exacerbation. The local progression of the disease seemed to have no effect on the height of the fever. These cases verified former observations which had shown that simple meningitis was characterized by a higher temperature than tubercular meningitis. Convulsive attacks appeared to have no appreciable effect on the temperature curve, the greatest increase being caused by complications, especially of the lung and abdomen, while, with general military tuberculosis, both high and low temperatures occurred. Tubercle of the cerebellum was always accompanied by a rather low grade of fever. Finally, the author speaks of the great worth of the temperature curve for differential diagnosis and for the exclusion of complications.

#### CHYLOUS EXUDATION IN ABDOMEN.<sup>7</sup>

Letulle reports the case of a boy eight years old suffering from mitral disease, where puncture of the abdomen presented an enormous quantity of emulsified fat, a few white corpuscles and a large number of red corpuscles. An analysis of his own cases and others leads him to the following conclusions: (1) All the published cases of chylous ascites, where an autopsy has been made, were caused by chronic tuberculous, carcinomatous, or simple fibrinous peritonitis. (2) The existence of inflammatory changes is a constant factor in the beginning of a

chylous exudation of the peritoneum. (3) The fatty metamorphosis of the inflammatory products is sufficiently probable to account for the formation of the large quantities of emulsified fat which is found suspended in the peritoneal fluid.

#### TWO EPIDEMICS OF VARICELLA.<sup>8</sup>

Ollivier reports his observations on two epidemics of varicella, occurring in Paris, in both of which in the beginning the disease was suspected to be variola. The first occurred in the spring, and its starting-point could not with any certainty be determined. Most of the children belonged to poor families whose dwellings consisted of one badly ventilated room. The infection spread from one child to another, and where one member of the family was attacked all took the disease excepting the adults, who escaped with only one exception, where a mother forty years of age took the disease from her nursing infant. Vaccination appeared to have no influence on the disease; out of thirty-four cases thirty-one presented well-marked vaccination cicatrices; the remaining three were under one year and did not have the disease more severely than the others.

The efflorescence usually began on the forehead and then spread to the face and limbs, leaving no trace and seldom presenting more than thirty to fifty vesicles. The incubation was from twelve to fifteen days, and recovery took place in every case.

The second epidemic presented the same characteristics, simulating variola, benign in its course, unaffected by vaccination, not attacking adults.

#### VARICELLA FOLLOWED BY NEPHRITIS.

Professor Henoch, from the autumn of 1883 to the spring of 1884, has observed and reported<sup>9</sup> four cases, where an intense albuminuria developed in the course of an attack of varicella from eight to fourteen days after the appearance of the efflorescence. One case ended fatally and the autopsy showed the existence of nephritis and hypertrophy of the left ventricle.

Dr. D. Semtschenko publishes<sup>10</sup> a case of varicella followed by acute parenchymatous nephritis, which is very similar to the youngest of Henoch's cases. A well-nourished girl three and a half years old, who in the previous year had had an attack of variola, developed a varicella after a prodromal stage of slight feverishness lasting for three days. Just before the appearance of the efflorescence, high fever with delirium was observed. The exanthem spread over the whole body but was not unusually profuse. After three days the vesicles were almost dried up, but the fever returned and oedema of the face and feet appeared.

The urine contained albumen and casts. The fever disappeared in two days, and the albumen became lessened in amount and entirely disappeared in nine days.

Rasch<sup>11</sup> also reports the case of a boy two years old, who after a few days of slight prodromal symptoms developed an efflorescence of varicella on

Boll. della R. Acad. Med. di Roma, VII. 9. Jahrb. f. Kinderheilk., xlii, 11.

\* Rev. de Med. 1884, 1-4.

<sup>9</sup> Berlin. Klin. Wochenschrift, 2, 1884. Jahrb. f. Kinderheilk., xxi, 4.

<sup>10</sup> Wratow, 1884, No. 12. Jahrb. für Kinderheilk., xxi, 3.

<sup>11</sup> Tidsskr. f. prakt. Med. iv, 1884, 4.

September 3, 1865; on the 11th, swelling of the face was observed, drowsiness, weakness, thirst, and loss of appetite; on the 17th there was also slight œdema of the legs. The urine contained albumen, blood corpuscles, and casts; the œdema disappeared on the twenty-first of September, and the urine became normal by the twenty-fourth of September. A sister of the patient at the same time had an attack of varicella running the usual course.

#### INCREASED MORTALITY FROM MEASLES IN NEW YORK.<sup>12</sup>

Measles is usually considered a disease of such slight import, and the necessity of careful isolation so often ignored, that the report concerning the recent increase of the disease in New York City, presented to the Board of Health, on March 3d, by Chief Inspector James B. Taylor, seems worthy of record. The report for four months is as follows:

	Nov.	Dec.	Jan.	Feb.	Total.
Cases . . .	385	484	743	540	2,152
Deaths . . .	60	75	157	111	403

The report is made from the returns of physicians, but cases are not always returned unless the patients die. In one public institution containing 200 infants, there have been 157 cases and 65 deaths in four months. Dr. Taylor says that such a rate of mortality is almost unaccountable, and that if the same rate prevailed elsewhere it would prove measles to be the most virulent of all contagious diseases. It has taken the lead over all others during the past two months, even exceeding diphtheria, as there have been from the latter 531 cases and 234 deaths during the same period that 1,283 cases and 263 deaths occurred from measles.

#### INCREASED MORTALITY FROM MEASLES IN PARIS.<sup>13</sup>

Ollivier, in a report to the prefect of police, shows that the epidemics of measles in Paris are increasing in extension and danger, and that there has been a decided increase in the mortality of the disease during the last twenty years. His figures are as follows:—

Year of epidemic . . .	1865.	1869.	1873.	1879.	1883.
Deaths . . . . .	313	510	503	917	1,068

Most of the deaths were caused by a complicating bronchopneumonia, and the death-rate would have been much greater if those cases could have been included who, at a later date, developed chronic pneumonia and tuberculosis of the lung. The author also emphasizes the necessity and importance of the early isolation of all cases.

#### ACUTE LARYNGITIS ACCOMPANYING MEASLES.<sup>14</sup>

Tiffany reports the following case:—

A boy, having measles, during the stage of irruption suffered from well-marked laryngeal stenosis. No membrane could be seen. When nearly dead tracheotomy was performed, which immediately relieved the symptoms. He died, however, some hours afterward from capillary bronchitis.

#### PERNICIOUS ANÆMIA IN A CHILD FIVE YEARS OLD.<sup>15</sup>

Dr. Adolphe Kjellberg opens a paper, in which he gives the history of this case, by stating that pernicious anæmia is of greater extent than was believed at the time when Biernar called attention to it by his description of the disease; that it is chiefly seen at mature age; that it runs up to the period of old age; but that, so far as childhood is concerned, only one case has been thus far reported, that a child eleven years old, by Quinke. (E. H. Bradford reported a case, in a girl eleven years old, in the *Boston Medical and Surgical Journal*, October 22, 1874, and H. C. Haven the case of a girl aged ten years, in the *Archives of Pediatrics*, December 15, 1884.) After having mentioned the principal symptoms of Quinke's case, he gives the history of his own case, which was a boy five years of age, who entered the hospital in Stockholm, April 9, 1883. The case was especially remarkable for its rapid course and very characteristic symptoms, such as discoloration of the skin, which became of a yellowish waxy color, pallor of the lips, great prostration, asthma on the least exertion, palpitations, intense anæmic *bruit*, retinal hemorrhages, watery-looking blood, and the reduction of the number of red disks to 0.571 million per cubic millimeter. The post-mortem appearances were also very characteristic: extensive fatty degeneration of the muscular structure of the heart, excessive pallor of the cerebral substance, hemorrhages of the cerebellum, pericardium, pleura, lungs, and peritoneum, and fatty degeneration of the epithelium of the renal tubules. From the knowledge gained from Quinke's case and his own, Kjellberg concludes that pernicious anæmia presents the same symptomatology in childhood as in adult life. This case throws but little light on the etiology of pernicious anæmia, and gives no ground for the hypothesis that this disease is the result of a life of privation and of insufficient nutrition, for this child was in comparatively good circumstances. Kjellberg is rather inclined to indorse the opinion of Warfringe that pernicious anæmia should be considered as an infectious disease. His patient was put on arsenic, with nourishing food, but with no noticeable result.

#### PEMPHIGUS NEONATORUM.<sup>16</sup>

C. Blomberg reports the case of a girl six days old, who had an efflorescence of pemphigus, beginning on the lower legs and quickly spreading to the thighs, abdomen, and front of thorax: later the face, arms, and head were attacked, only a few bullæ appearing on the back. The lesions developed quickly on a previously normal skin and disappeared after two or three days, leaving a moist, reddened corium, crusts only appearing on the face. One of the bullæ on the head was as large as a hazel-nut; on the right foot one bulla covered all the toes and the sole; the sole of the left foot was covered by three bullæ. Entire recovery took place. Three servant girls in the family, who took care of the child and washed its clothes, were affected in from three to six days with the same efflorescence on their fingers and on the backs of

<sup>12</sup> Medical News, March 7, 1886.

their hands. Another child and the mother had a few bullæ develop on them. Blomberg inoculated himself on the forearm with fluid from the bullæ, and on the following day a similar efflorescence appeared, which dried up in three days.

#### SYPHILIS HEREDITARIA TARDA.<sup>17</sup>

Barthélemy upholds the existence of a late appearance of hereditary syphilis, especially on the ground of the frequent observations made by him of syphilitic disease of the liver found in older children as well as in younger. He enumerates thirty-two cases of children between two and thirteen years of age, the greater number being from five to nine years, affected by different forms of syphilitic liver, which he divides as follows:—

(1) Congestive form. Symptoms: increased liver dulness, hepatic tenderness, sometimes slight icterus, recovery under anti-syphilitic treatment.

(2) Diffuse interstitial hepatitis. Symptoms: great hepatic tenderness, emaciation of high grade, severe dyspeptic symptoms, and ascites; icterus usually absent.

(3) Gummous form, usually a combined disease of the liver and spleen, and often also the lung, the disease of the liver being only seldom detected by physical examination; usually neither icterus nor ascites present; unfavorable prognosis, life usually threatened through the combined disease of the lungs and kidneys.

(4) Amyloid. The most severe form of syphilitic disease of liver.

Barthélemy concludes that hereditary syphilis, not only in early childhood, but also after the beginning of the second period of childhood, presents the most frequent causes of hepatic disease.

### Reports of Societies.

#### PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M.D., SECRETARY.

APRIL 13, 1885. The President, Dr. F. W. DRAPER, in the chair.

Dr. H. C. HAYES read a paper entitled

#### A STUDY OF INFANT FEEDING,

of which publication is reserved.

Dr. F. S. BILLINGS, V.S., demonstrated, by invitation, several

#### CULTIVATIONS OF THE CHOLERA BACILLUS AND OF OTHER ALLIED MICRO-ORGANISMS,

showing a number of test-tubes containing cultivations of different ages, both of the cholera and of other bacilli likely to be confounded with it. Especially the marked difference in the development of the bacilli of Asiatic cholera and of cholera morbus was shown, although Dr. Billings stated that he doubted if it were possible to make a diagnosis by the microscope alone, unaided by artificial cultivations. The behavior of bacteria in different cultivating media is of much diagnostic value, as many of them grow in a peculiar manner in a medium of

known specific reaction. He stated the advantages of solid over fluid media, and explained their preparation, together with the great care needed in the work and the many little slips that might make it worthless. In his opinion Koch's bacillus has always been found, when sought in undoubted cases of cholera, by competent observers with competent instruments. It has never been found anywhere else. Although the remaining proof, cultivation of the disease by means of the bacilli, has not yet been made, still in the present early state of our knowledge of the subject, and the known difficulties in the way of experiment, we have no reason for declining to accept the bacillus as the cause of cholera. Dr. Billings thinks that, by its aid, a certain diagnosis can be made in twenty-four hours, and he is of the opinion that it would be well at the present time if boards of health were to train experts in the examination.

April 27th, the President, Dr. F. W. DRAPER, in the chair.

#### FIBROID TUMOR OF THE OVARY, WEIGHING TWENTY-TWO POUNDS; LIPOMA OF THE THIGH, WEIGHING TWELVE POUNDS; SARCOMA OF THE LEG.

Dr. JOHN HOMANS showed the specimens, and said that the fibroid tumor of the ovary is interesting from its rarity. He had never before seen one, and Mr. J. Knowsley Thornton, of London, had his first one last autumn. Dr. Homans's patient was thirty years old, and married, but without children. She had noticed the swelling for about a year. When Dr. Homans examined her recently there was in the left iliac and lumbar regions a very hard, dense tumor, and the rest of the abdomen seemed to be occupied by a cystic growth. The abdominal cavity was so full that it was hard to say whether the tumor was uterine or not; but on moving it the uterus moved, though not as if it were incorporated with it. As Dr. Goodell and Dr. Walker, of Philadelphia, had examined her at an earlier stage of the case, the speaker had written to Dr. Goodell for his notes. Dr. Goodell replied that his notes were somewhat scanty, but that there was a dense, hard tumor in the left of the abdomen; that the uterus was at that time three and a half inches deep, and that he thought that the tumor and the uterus were movable independently of each other. He was, therefore, in doubt as to whether it was a uterine or an ovarian tumor. Dr. Homans, bearing in mind the unfavorable percentage of his attempts to remove uterine fibroids by laparotomy, told the patient that while the chances in such operations were rather less than equal for recovery, yet that the patient's health and strength being good, a most important factor, that he was inclined to operate. The tumor was removed six days ago. On opening the abdominal cavity the omentum was found to cover the tumor and to be adherent to the pubes. This is always an embarrassing complication. He opened through it and gradually enlarged the wound upward, tying the bleeding points. A cyst was now in view and this was tapped, evacuating about six pounds of clear, dark fluid, resembling that from a fibro-cystic tumor of the uterus. The tumor being still too large to come through the abdominal opening, Dr. Homans

<sup>17</sup> Archives Générales de Médecine, Mai et Juin, 1884.

passed his hand behind the cyst-wall and found another cyst, which he also tapped, getting five pounds more of the same fluid. He now pulled out the cysts and with them the solid tumor, which proved to be connected with the right broad ligament and Fallopian tube, and was an ovarian tumor. He treated the pedicle in the usual way, tied the omentum where it was bleeding, and returned it to the cavity. While this was going on, the abdominal walls were held together by an assistant, who kept the bowels covered up. Little points like this diminish the shock and have an effect on the result. The tumor, together with the fluid, weighed twenty-two pounds, and the patient is making a good recovery, the pulse and temperature being to-day normal.

Dr. HOMANS also showed a fatty tumor of twenty-five years' standing and twelve pounds' weight, removed from a patient of seventy-one, six or seven weeks ago. There was an ulcer over the tumor, which was on the left thigh and extended from the groin to the patella. The tumor came out easily, and the patient did well for a few days, but had septicæmia afterward, and died in five weeks, the age having probably as much to do with the death as anything.

Dr. HOMANS also showed a sarcoma from the leg of a professional baseball player, who had been struck by a ball on the head of the fibula five years ago, since which the tumor had gradually grown. Dr. HOMANS began to amputate above the condyles of the femur, but finding a cord of sarcoma running up the thigh he cut two inches higher, again finding sarcoma. The glands in the groin were slightly enlarged. He then amputated in the middle of the thigh. The patient recovered. At the same time he had a case of round-celled sarcoma in the testicle of a policeman who had been kicked in that organ, both these cases being apparently developed by the blow.

Dr. FRANCIS MINOT asked as to the condition of the ovarian patient.

Dr. HOMANS said that she was beginning to emaciate. She could not stoop because of the size of the tumor, which weighed, including the fluid, thirty-three pounds. He believed that menstruation had been regular.

Dr. W. J. OTIS said that he had a patient with cancer of the rectum, which was supposed by the sufferer to be caused by a kick received in a fight. Dr. Otis did not mean to say that that was really the exciting cause, but no other could be found.

Dr. O. W. DOE read a paper on

#### PSEUDO-MEMBRANOUS ENTERITIS.

Dr. F. W. GOSS said that quite a number of cases had been reported by Dr. Boardman and others since he read a paper on this affection before the Society nearly four years ago. Patients who suffer from the malady are almost always debilitated. Whether their nervous prostration is a cause or a consequence of the disease has been a matter of diversity of opinion. The pain and discomfort which accompany paroxysms of the trouble may account for the nervous prostration of the patients. The length of the pieces of the membrane-like discharge in the case reported by Dr. Doe—twenty-seven inches—is

unusual, though not unique. Occasionally one is fortunate enough to escape with but a single attack, but the rule is for recurrences at intervals of months or years. The first of the cases reported by him four years ago has since had a repetition of the malady about once a year; the second case has not had any severe paroxysms, though from time to time there have been small quantities of the peculiar discharge. Some have held that the trouble is due to habitual constipation, but recurrences take place where the bowels have been kept by mild laxatives in a tolerably regular condition. As stated in his own paper he thought the term enteritis, as applied to the disease, to be of doubtful propriety, as marked inflammatory symptoms are not usually observed in the attacks. In fact, we know very little of the pathology of the disease, as it is rarely fatal, and no very satisfactory post-mortem observations have been recorded.

Dr. J. B. AYER suggested the use of occasional doses of castor oil; for the reason that he thinks it has a peculiarly good effect when given to patients with dysentery in which there is a local disease of the intestine, as there seems to be here.

Dr. C. M. GREEN spoke of a case he had seen, in his service at the City Hospital, in which apparently there had originally existed a

#### DOUBLE VAGINA.

Beginning just within the introitus vaginae there extended along the posterior vaginal wall in the median line a partial septum about three sixteenths of an inch in thickness: the height of the septum at the introitus was about three fourths of an inch, diminishing gradually to perhaps one fourth of an inch at the posterior lip of the cervix, to the centre of which the septum was firmly attached. In the median line of the anterior vaginal wall, beginning just within the introitus, was a fine linear cicatrix about two inches in length indicating the probable place of attachment of a part, at least, of the now free border of the septum. The uterus was normal.

The patient did not begin to menstruate until she was eighteen years old; she was never regular and always suffered more or less menstrual pain until after the birth of her first child, a year and a half ago, since which time the dysmenorrhea has very much diminished. She carried her child to full term, and her labor lasted three days; she described the pains of the expulsive stage as sharp and tearing in character. The child was delivered without instrumental assistance, but was stillborn.

#### CHICAGO MEDICAL SOCIETY.

LESTER H. MONTGOMERY, M.D., SECRETARY.

STATED meeting, April 20, 1885. The Vice-President, C. W. PERRY, M.D., in the chair.

Dr. H. GRABLE read a paper entitled

NERVOUS SYMPTOMS DUE TO OVERLOOKED ANOMALIES OF THE EYE AND EAR,

in which he referred to a classification of diseases according to their etiology which he proposed at the last meeting of the Illinois State Medical Society, in 1884.

The paper now read contained reference to several cases which had come under the author's own observation. The special interest of these cases lies in the fact that the local eye and ear symptoms were so insignificant that the primary trouble was either wholly overlooked, or was not supposed to have any connection with the more annoying nervous symptoms in other parts of the body.

The only region of the eye the irritation of which the author has known to cause disturbance in distant parts of the body is the ciliary muscle. The condition of undue strain to which this muscle is subjected in hypermetropia and astigmatism is perhaps a prominent aetiological factor in these cases. The most frequent symptom caused by eye-strain is headache, which is always frontal or temporal, though in nervous subjects it may extend over the whole head, and even to the back of the neck. In some cases the pain is constant, in others it occurs only after undue exertion of the eyes. In very many cases moderate pain exists all the time, but it is increased by work. It is usually described as a dull, aching pain. This form of headache has often been permanently removed by the use of spectacles. In some cases of astigmatism it is necessary to keep the ciliary muscle paralyzed by the application of atropia for a few days in order to have the glasses fitted. The reader could not corroborate the view that hemicrania is sometimes due to refractive anomalies, or rather to the eye-strain produced by them. He has never seen migraine cured by glasses alone, though it is not to be doubted that the correction of the strain will facilitate the cure or mitigate the migraine at any rate. Dizziness, with or without headache, is a common result of eye-strain; there is rarely, however, any danger of falling or reeling, and it is more commonly a dazed feeling, or a difficulty of concentrating both thought and sight upon the same object.

Gastric disturbance sometimes occurs as a consequence of refractive difficulties; patients sometimes complain that an eye-strain of which they are conscious will produce a feeling of uneasiness in the region of the stomach. The reader cited the case of a man, thirty-three years of age, for whom he had prescribed moderately strong concave cylinders in spectacle frames, on account of intense eye-strain, headache, and dizziness. When the patient was seen, three years later, he was well, so far as his eyes were concerned. A few months ago, however, he had a new pair of glasses made, and since that time he has felt somewhat dazed at times, and frequently slightly nauseated; he had lost his appetite, and rather loathed his food. The new glasses were in eye-glass frames, and the direction of the axes was not proper or constant. On the patient returning to the spectacle frames all symptoms of gastric disturbance disappeared.

Aural lesions may also cause disturbance in distant parts of the body. Dr. Grandle has notes of fifteen cases in which treatment of ear trouble caused symptoms in other parts of the body to disappear. One case was that of a young man in whom an eczema of the meatus caused troublesome cough for some time; an application of a strong solution of nitrate of silver to the well-denuded and scraped surface caused the cough to disappear entire-

ly. Another case was that of a child in which the removal of a plug of exfoliated epithelium from the external auditory meatus stopped regular attacks of spasmodic cough. The most frequent reflex lesion caused by this disease of the ear (epithelial exfoliation) is headache, generally diffuse, and often very persistent. This affection of the epithelium is always accompanied by some interference with the permeability of the Eustachian tube. Two cases of neuralgia of the fifth nerve, on the affected side, leading to the detection of the ear trouble, were cited.

While vertigo quite often accompanies any disease of the middle ear which increases the intralabyrinthine pressure, the writer has never observed dizziness unless the patient was aware of the ear trouble, except in very young children. He mentioned the case of clonic spasm of the eyelid produced by the presence of a bead in the ear, in a very young child, and also a case of spasmodic torticollis resulting from irritation of the external meatus in a child four years of age.

There was no discussion on this paper.

Dr. F. E. WAXHAM read a paper on

#### THE TREATMENT OF CROUP AND INTUBATION OF THE LARYNX.

After giving an exhaustive summary of the many remedies for the treatment of this affection, the reader said that to Dr. J. O'Dwyer, of New York, belongs the credit of originating this bold and ingenious device for treating croup. Concerning this method he drew the following conclusions: (1) With a little dexterity and practice it can be easily and quickly performed and without danger; (2) the patient is not mutilated or disfigured; (3) there is no wound to cause shock, or to become the source of septic infection; (4) the tube can be worn much more easily than the ordinary tracheotomy cannula, and coughing and expectoration are just as easy; (5) it does not require the close care of a tracheotomy; (6) the air that reaches the lungs is warmed by its contact with the upper air-passages, and is not so likely to cause bronchitis or pneumonia; (7) parents will consent to tubing much more readily than to tracheotomy.

Dr. F. O. STOKCROX stated that three years ago, in Vienna, he began making experiments with the idea of devising something to replace or take the place of tracheotomy in the treatment of croup. His first idea was to fasten in a male silver catheter passed through the mouth, but he soon found that would not do, as it prevented the taking of food and was liable to inflict injury by the free end coming in contact with external objects. Then he cut off a piece of silver tubing and turned a flange on it, the flange to rest on the vocal cords; but that would not do, as it was soon coughed out, the tube being only an inch long. Next he made a triangular tube the shape of the glottis when at forced inspiration. This was retained better, but it was finally coughed up also. After that he made a tube of the same shape, with the addition of two spring flanges to spring out below the vocal cords; this was retained, but caused a good deal of inflammation, and could only be removed with difficulty,

as the mucous membrane would swell in around the flange.

All of his experiments were made without any knowledge of the experiments of Dr. O'Dwyer. Honor to whom honor is due, and Dr. O'Dwyer, he thought, has apparently successfully solved the problem of tubing the larynx.

Dr. D. A. K. STEELE corroborated the statement of Dr. Waxham, so far as immediate relief was afforded to a child he had seen in consultation with him, and that the child took fluids from a spoon slowly and swallowed semi-solid boluses of food.

Dr. EDMUND ANDREWS had not tried tubing the larynx. He believed it was an important operation, and hopes it may prove to be the one *par excellence*, at least until something better is invented. The speaker inquired of Dr. Stockton if any suspicion or probability exists that the lower flange might slip down into the trachea, or is it liable to be drawn into it, or if the weight of the tube is sufficient to overcome the resistant nature of the vocal cords.

Dr. STOCKTON replied, No, there is no danger of the tube being drawn into the trachea, owing to the resistant nature of the vocal cords; and, again, the length of the tube is such that it nearly reaches the bifurcation. The tube used is not liable to fill up with membrane. As they are gold-plated and cannot corrode, their inner surface is perfectly smooth, and will not afford lodgment to foreign bodies that would plug the tube and cause it to be drawn into the trachea by inspiration.

Dr. WAXHAM closed the debate by stating that the effort to remove the tube will cause contraction of the glottis. The longer the tube remains the less danger there will be of expelling it.

#### PATHOLOGICAL SOCIETY OF PHILADELPHIA.

THURSDAY evening, April 9, 1885. The President, Dr. SHAKESPEARE, in the chair.

##### CASE OF ABSCESS IN THE SUPRA-RENAL CAPSULES.

By Dr. EDWARD T. BRUEN.

The accompanying specimens were removed from the body of Mary S., aged fifty-seven, who died in the Philadelphia Hospital. Two weeks before death she was admitted to the medical ward, and within a few days a circumscribed swelling in the left femoral region developed into an extensive abscess. Death occurred apparently from septicaemia. No satisfactory previous history could be obtained.

Post-mortem examination disclosed: Left kidney one third larger than normal. Capsule quite adherent. Upon removal the section showed a granulated surface, pale and mottled. The pelvis of the kidney much dilated, that is, general evidences of parenchymatous nephritis.

Supra-renal body very much enlarged, and closely united with the kidney by strong inflammatory adhesions. It was of the size and shape of a hen's egg. On section showed cystic degeneration, or softening of the medullary portion, the contents of the cyst being a thick, purulent, creamy liquid filled with cheesy particles.

The cortical portion shows fibroid thickening, forming a dense connective-tissue wall one fourth to half an inch in diameter.

The right kidney was of normal size, but showed similar changes to the left.

Right supra-renal body normal.

Other abdominal organs normal. No peritonitis. Abdominal and other lymph glands throughout the body normal.

Thoracic organs normal.

On examination of left femoral region a large tumor was found. Upon section pus exuded freely, and a large abscess was discovered between the extensors and adductors and lying beneath the sartorius. The abscess extended into the hip-joint; the acetabulum and periosteum of the head of femur were eroded.

The comparative rarity of disease of the supra-renal body lends an interest to any lesions affecting it. Dr. SHAKESPEARE has made some sections of the capsule of this tumor without finding any tubercular structure. There was no bronzing of the skin, nor any other symptoms than those naturally to be expected in association with a large abscess, such as was found in this case. These facts, together with the unilateral character of the lesion, incline me to consider this specimen as one of abscess in the supra-renal body.

Dr. O'HARA asked whether this might not be a surviving abscess left after the absorption of other pus centres, as he thought sometimes occurred.

Dr. NANCREE combated this novel view, contending that while fugitive visceral congestions sometimes occurred in pyæmia, which readily disappeared, as well as certain collections of white blood cells in the thecae of tendons and the bursa contiguous to joints, yet he did not believe that septic emboli producing infarcts could be absorbed, as maintained by Dr. O'Hara. Besides, if this explanation were correct, the clinical history should indicate something of the sort, which it did not, being one of *septicaemia*, not pyæmia.

Dr. BRUEN said that there were one or two points of interest upon which he had not touched in the notes already read. The patient had led a dissipated life, having been brought into the hospital from one of the "slums" of the city. He had supposed that the woman had received some injury, such as a blow, which had given rise to the abscess in the groin, and she had died with symptoms of septicaemia. He had therefore regarded the abscess in the renal capsule as secondary. The localization of the pathological process in but one capsule, the absence of bronzing of the skin, vomiting, or vaso-motor disorder, separated the case from Addison's disease. Indeed, it may be said the *ensemble* of the latter disease was wanting. Cases of Addison's disease have been described as being associated with abscess, but the disease was always bilateral and in association with a special train of symptoms and with the absence of other pathological processes in the system. The most valuable compilation of cases of diseases of the supra-renal capsules up to the year 1866 could be found in the seventeenth volume of "The Transactions of the London Pathological Society," 196 cases having been collected by Dr. Greenhow.

SPECIMEN OF ANEURISM OF THE AORTA, WITH RUPTURE INTO THE TRACHEA IN TWO PLACES, AND PERFORATION OF THE OESOPHAGUS.

Presented by Dr. OSLER.

W. J., aged fifty-four years, colored, a teamster by occupation, and accustomed to do heavy work. Has been healthy and strong; no history of syphilis. In August, 1882, he began to suffer with pains in the chest and left shoulder, but he did not have any serious inconvenience until September, 1883, when he was attacked with cough and thoracic trouble, possibly pulmonary, which kept him in the house and in bed for several months. It was not until May of last year that he was able to work. Since July he has had at times attacks of shortness of breath with wheezing, and often at night has had to sit up in bed. Within the past three weeks the pains in the shoulder and down the left arm have become very severe, and the cough and shortness of breath have increased. Note on admission was as follows: Well-built man, face thin, general *musculature* good. Inspiration rough and noisy, expiration loud and harsh, and often accompanied by a brazen, laryngeal cough. Respiration, eighteen per minute; can rest in the recumbent position. On inspection the left side of the neck is much flattened, especially above the clavicle, and the sternomastoid muscle on that side is evidently atrophied. Apex-beat visible in normal position; no abnormal pulsation; slight visible pulsation in vessels of neck. Palpation in the ordinary way negative, but on firm pressure with one palm on the upper bone of sternum and the other on the back, a distinct impulse can be felt and the second sound is accentuated; deep pressure reveals pulsation above sternum and behind left sternoclavicular joint. Percussion reveals a slight area of dullness over left half of the manubrium sterni and beneath left sternoclavicular joint. Heart dullness not increased. Auscultation: heart sounds clear. At sternoclavicular joint, when the breath was held, there is a soft double murmur, the diastolic the louder, and the second sound seems markedly accentuated. These murmurs can be heard over the left carotid and in supra-sternal notch. The tugging at the trachea was marked on elevating the larynx; pupils equal. The left radial pulse is smaller than the right and is slightly retarded. Lungs negative; loud tracheal and bronchial stridor; no pressure signs on either bronchus. Patient expectorates much thin muco-serous fluid, which is blood-tinged, and at times there are more consistent sputa containing much blood. He was ordered to take twenty grains of potassium iodide three daily and to rest quietly in bed; no restriction as to diet. Laryngoscopic examination showed that the left cord was immobile. Within three weeks he was greatly benefited as regards the pains, cough, and wheezing, and the blood had disappeared from the sputum. Throughout February he remained very well, having occasional attacks of spasmodic coughing at night, which were relieved by spirits ether compound. His general health improved and he was allowed to get about the ward. Sputum occasionally tinged with blood. On March 19th he was shown to the class, and the following

changes noted: Slight increase in substernal dullness on firm percussion; more marked accentuation of second sound over this region; persistence of the double murmur, which was now also to be heard just to the right of the sternum and at the aortic cartilage, and at this point it was the loudest. No increase in the pulsation, but in certain lights a slight impulse at the upper part of the sternum was visible. At the beginning of the month he began to be more wheezy, the stridor was very marked, and the dyspnea became urgent, so that he had to sit up in bed. Sometimes these attacks would come on suddenly. On the 3d and 4th the dyspnea was severe and he got much weaker. On the 5th and 6th he spat up some bright blood, but not in any great amount, and gradually sank, dying at 9.30 P.M. The specimen removed by Dr. Hamaker shows an aneurism of the aortic arch which occupied a position between the first bone of the sternum and the spine, very firm, solid, and about the size of an orange. The entire arch is dilated, but the sac of the aneurism involves especially the upper posterior part and is lined with dense, yellow, fibrinous laminae. The orifices of the innominate and left carotid are free, that of the left subclavian is considerably narrowed by atheromatous ridges. The great veins are not compressed. The left recurrent laryngeal passes round the sac, is much stretched and looks thinned; the right is normal. The trachea is much compressed about the middle of its course, and the aneurism causes a marked bulging on the left side, where two perforations can be seen. The upper one, about six centimeters from the bifurcation, is only two or three millimeters in diameter, and the tissues about it are thickened, dark, and the mucosa somewhat fibroid. The lower orifice is smaller and looks more recent. Neither of these lead directly into the sac proper, but into a small pocket situated between the dense laminae of fibrin and the thinned tracheal wall. On inspecting the oesophagus, an oval perforation was found seven centimeters from the cricoid cartilage, which communicated directly with the sac, but was partially blocked with fibrinous clots. The stomach was found distended with fresh clots and there was much altered blood in the small intestine. Collapse and congestion of the bases were the only changes in the lungs. The heart was not hypertrophied; valves were normal, muscle substance flabby and in a state of fatty degeneration and brown atrophy.

The points of interest in this case were the repeated bleedings extending over several months, and the associated wasting of the muscles of left side of the neck. At first the bleeding was looked upon as an indication that erosion of the trachea had occurred, but subsequently it was thought more probable that it came from swollen mucosa at the site of the compression. No doubt the first supposition was the correct one, as the upper of the perforations had probably been the source of the bleeding, but the firm, leathery clots effectually prevented any profuse hemorrhage. The final bleeding into the oesophagus also took place very slowly, probably during the last thirty-one hours of life, as there was dark, much altered blood in the ileum. It is impossible to say upon what the atrophy of the neck muscles depended, as no care-

ful dissection was made of the nerves in that region; possibly the sympathetic was affected, but there was no difference of the pupils.

In reply to a question, Dr. Osler said that the iodide of potassium was given chiefly with a view to relieving the pains, and it had the desired effect.

#### A FOUR-LOBED LUNG.

Dr. W. A. EDWARDS read an elaborate description of a specimen of the lungs where the right had four lobes. The paper was accompanied by a careful drawing of the specimen, which had, unfortunately, been destroyed by the evaporation of the preserving fluid.

Dr. OSLER asked whether there had been any dissection made of the bronchi and bloodvessels of the abnormal lobe.

Dr. EDWARDS replied that no very careful dissection had been made, as he wished to preserve so rare a specimen, but, as far as his examination went, he could see nothing abnormal.

Dr. H. R. WILKINSON presented a specimen removed by amputation from a patient in the University Hospital, under the care of Professor Ashurst, which showed a marked degeneration of the knee-joint, resulting from inflammation of that articulation.

The patient from whom this specimen was removed was a man aged forty years, who, three years before, had received a slight injury of the right knee, which caused him more or less trouble up to January, 1885. At this time, while at his work, he twisted the affected knee; this injury was followed by an attack of acute inflammation which went on to suppuration and destruction of the cartilages. The patient, when admitted to the hospital, had a high temperature, profuse sweats, and a rapid and feeble pulse. His condition was so urgent that it was deemed advisable to remove the part by amputation rather than to make use of the more conservative operation, excision of the knee-joint.

#### REPORT OF THE PROCEEDINGS AT THE THIRTY-SIXTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION AT NEW ORLEANS.

##### GENERAL SESSION. — FOURTH DAY.

The following nominations completed the list from the Committee:—

*For Trustees of the Journal.*— Drs. J. M. Toner, of Washington, D.C.; J. H. Hollister, of Chicago, Illinois; E. M. Moore, of Rochester, New York.

*Committee of Arrangements.*— For Chairman, Dr. LeGrand Atwood, of St. Louis, Mo., Assistant Secretary, Dr. William Glasgow, of St. Louis, Judicial Council, Dr. J. K. Bartlett, of Milwaukee, Wis. (*vice* Dr. Brodie, of Detroit, resigned).

The following resolution, referred to the Association by the Section on State Medicine, was adopted:—

*Resolved,* That the Section on State Medicine heartily recommends the appointment in each State of a State Board of Medical Examiners and Licensers.

That the Committee appointed by the Association shall construct and forward to each State Society the form of a bill, the passage of which by the Legislatures these Societies shall be requested to urge strongly.

Dr. KELLER, of Arkansas, asked that his resolution in regard to

##### CREMATION.

which has been lying on the table for some years, be considered. The resolution, which was as follows, was referred to a committee to report next year:—

*Resolved,* That in the near future, if not now, cremation will become a sanitary need in the cities.

Dr. J. A. WHITE, of Richmond, Va., read the address in

##### OPHTHALMOLOGY, OTOTOLOGY, AND LARYNGOLOGY.

in which he considered the advances in these different departments during the year.

Cocaine he considered almost useless in children and obstinate patients, when the eye is greatly inflamed, and in all lengthy operations.

Dr. J. H. PORE, of Texas, then delivered the address on

##### DISEASES OF CHILDREN.

in which he treated specially of the treatment of diphtheria by bichloride of mercury, and of the etiology of rickets and the part prolonged nursing takes in its production.

##### A SECTION OF MEDICAL JURISPRUDENCE.

Dr. L. N. QUIMBY, of Jersey City, New Jersey, reported from the committee to consider the President's suggestion in his address that a section on forensic medicine be added to the present list of sections, a recommendation that such a section be formed and styled a Section on Medical Jurisprudence, and that the Constitution be amended to admit of this addition to the existing sections.

Dr. TOXER, of Washington, D.C., Chairman of the Committee on Necrology, stated that all deaths had been promptly printed in the *Journal* of the Association since its establishment.

An attempt to separate the Section on Ophthalmology, etc., into two separate sections was defeated.

##### THE NOMINATING COMMITTEE.

The resolution of Dr. Cochrane offered last year to the effect that the Association disapproves of the selection by the Nominating Committee of members of their own committee for the various offices of the Association was warmly discussed and laid upon the table.

Dr. H. N. BYRD, of Quincy, Ill., offered a resolution to the effect that each State Medical Society shall appoint annually a member of the Nominating Committee and three alternates, the members thus appointed by the several States to constitute the annual Committee on Nominations of the Association. Laid over for one year.

Dr. M. H. HENRY was appointed a delegate to the British Medical Association.

The usual vote of thanks of the Association for the courtesies from the profession and citizens of New Orleans, mentioned especially Dr. and Mrs. T.

<sup>1</sup> Concluded from page 453.

G. Richardson, Mr. and Mrs. Cartwright Eastis, the Jockey Club, the Washington Artillery, and the Directors of the Tulane University.

#### MEDICAL SECTION. CONCLUSION OF SECOND DAY.

One feature of this day's proceedings was a paper by Dr. N. S. Davis, of Chicago, upon

#### THE RELATION OF CLINICAL FACTS TO THE QUESTION OF THE CONTAGIOUSNESS OF PHTHISIS PULMONALIS.

In this essay, Dr. Davis treated anew the well-worn arguments against the germ theory of tuberculosis and held up the famous bacilli of that disease to ridicule. He quoted statistics to prove the exemption of hospital attendants from contagion, and laughed at inoculation experiments. Supposing that tuberculosis does follow the inoculation of bacilli, who can assert that these germs are sown pure and undefiled of other associated matter deleterious in its nature? and who can say that the poison may not be the excreta of the bacilli rather than the creature itself? When any one shall obtain an individual bacillus, and holding him by the tail isolated from all impurities shall then produce tuberculosis by implanting him in previously healthy tissue, Dr. Davis will allow the specific character of tuberculosis.

#### DISCUSSION.

Dr. LYNCH, of Maryland, endorsed the views of Dr. Davis in the discussion of this paper.

Dr. WHITTAKER, of Cincinnati, said that it was hard for him to understand how any one who had made himself familiar with the recent literature of tuberculosis could refrain from subscribing to the view that this disease is as directly due to the bacillus as is trichinosis to the trichina spiralis. He would as soon think of reciting the letters of the alphabet as naming over the experiments which had led up to the knowledge of the fact that this was a specific disease. He would allow himself only to say that Cohnheim, who was the most authoritative dissenter from this view, finally had to retract his opposition and admit the specific nature of it. The discovery of the cause of it by Robert Koch did not rest simply upon the presence of the bacillus, but upon his ability to isolate it, cultivate it, and inoculate it. There are no facts in our profession which have such a broad foundation as this, not even those that support trichinosis or scabies.

The speaker would notice only two points offered by the essayist. One to the effect that if the disease be contagious, there should be more victims. Now it is already admitted that tuberculosis destroys two sevenths of mankind. These are the fatal cases, but every clinician knows that the majority of cases of tuberculosis do not die. At least every pathologist knows that in the vast majority of autopsies upon patients dead from other diseases tuberculous nodules, cicatrices, or apical pleuritic adhesions are found in the lungs. It is perfectly safe to say that more than half of mankind are at some time or other affected with tuberculosis. It is an exception to find upon the post-mortem table a pair of lungs absolutely free of evidence of existing or pre-existing tuberculosis. It is useless to dilate upon a fact so well known as this.

The second point was the alleged exemption of attendants and other patients in the wards of hospitals common to all diseases where tuberculous patients were always present. Now this same remark has been made of other diseases, notably by Murchison of typhoid fever, which are admitted on all sides to be contagious. But aside from this fact, and of the more perfect ventilation of hospitals, and of the more prompt and perfect destruction of tuberculous products, the sputum is destroyed before it dries to be disseminated. The statement ignores absolutely the period of latency of tuberculosis. Did the essayist follow up for years the history of the attendants to know that none of them had tuberculosis? Do we not know of cases of scrofula, caries of the vertebrae, tuberculous joint affections, etc., that the development of these affections is often delayed for months or even years? Other seeds in the vegetable world may lie dormant for twelve years, the botanists tell us. We know that tubercle bacilli may be inoculated after six months' deprivation. Who shall say as yet how long these bacilli may lie latent awaiting the moment of fertilization to spring into growth?

The speaker declared that it was the greatest pride to him to know that all the main facts regarding tuberculosis, those that offer us hope in the extermination of this germ, which is preëminently the parasite of man, were made known to us long before the work of the scientists proper by the clinicians themselves. They who are familiar with the literature of tuberculosis will remember that William Budd, over a quarter of a century ago, proclaimed, in the clearest terms, the contagious nature of it, and also showed how easy it would be to stamp it out by the destruction of the products of the disease. It was because practitioners of medicine refused to believe the declarations of one of the most keen and far-sighted of their own number that they had to wait for demonstrations of the exact character of the specific and contagious element in that branch of the school of science which is itself the most exact and incontrovertible. Clinicians may ridicule the work of the experimenters with which they are not familiar, but they should hesitate to deride that of their fellows who had come to the same conclusions by bedside observations long before the modern science of mycology was known.

#### THIRD DAY.

The leading paper of this session was upon

#### CHOLERA AND ITS TREATMENT,

by Dr. J. H. Hollister, of Chicago. After a brief review of the history of cholera, the writer formulated his conclusion that it is not an endemic disease of America, but is imported from foreign countries. It is not transmitted by ocean or atmospheric currents, but is brought by individuals or by materials which have been in contact with cholera patients, and it never spreads inland from infected ports except along "the lines of travel." In regard to the nature of cholera Dr. Hollister inclined strongly to the theory of a specific cause but he felt that it is not yet proved that the comma bacillus is the particular germ. The causes which form the development of the disease are

warmth, atmospheric moisture, and the presence of organic substances in process of decomposition.

Dr. Hollister then discussed the importance of proper prophylactic measures — "whether we endeavor to estimate the value of human lives or the unnumbered millions of money involved in a widespread epidemic of cholera, we are prompted by motives which have scarcely a parallel, to the utmost of our effort, to educate our rulers and the masses of the people to the exigencies of the hour." The surveillance of ships and shores should be rigorous, and local authorities should exercise a strict surveillance of all its citizens. House-to-house inspection should be made and often repeated to abate all nuisances and control ignorant transgressions of the laws of health.

In regard to the care of individual cases of cholera, the writer said he had had extended experience with the disease during the epidemics of 1848, 1854, 1856, and 1873. "The inspiration of hope and confidence are primal necessities." The beginnings of the disease must be quickly brought under control. The slightest disturbance of the bowels must be attended to, and an early diagnosis will render remedies of most avail. "A hot bath for fifteen minutes, the quick envelopment of the entire body in dry hot flannel immediately after bath, the stimulation of the cutaneous surface with dry mustard and with friction under cover, artificial heat so applied as to secure, if possible, free perspiration,—these all conspire to divert the circulation and save from intestinal congestion. From this time the patient should be compelled *absolutely* to the recumbent position." The drinks should be bland and mucilaginous. Hot water is beneficial as a drink. No solid food should be allowed under any circumstances. Acidulated drinks are pleasant and beneficial. "Of all remedies to be administered internally I hesitate not to say that opium heads the list. Stimulants may be given in the stage of greater prostration. Camphor is one of the most valuable stimulants." Dr. H. does not believe in the hyperdromic injections of water.

The discussion was opened by a paper from PROF. AUSTIN FLINT, of New York, who heartily endorsed the germ theory of the disease. He thinks that opium has no competitor in the early stages of the disease, that is, *prior* to collapse. "It is a fair statement, perhaps, that a patient in the advanced stage of the disease has as good, if not a better, chance of recovery, if nothing potential be done in addition to maintaining absolute rest and the introduction of fluids as freely as the stomach will retain them."

Dr. N. S. DAVIS, of Chicago, said that he had studied the germ theory of cholera for a long time and had obtained as good comma bacilli from the serous discharges of ordinary diarrhoea as from choleraic discharges and he had no belief in the germ theory. He also disavowed belief in the contagiousness of cholera. In his experience a case occurs in one part of the city and the next appears at some other remote part of the city. They need have no connection with each other, or with shipping or with any common cause. He does not believe, therefore, in quarantine or other restrictive measures. It is idle to talk of stamping out the

disease by such measures. He thinks the disease arises from condition of the soil and atmosphere. Fresh free rains repress cholera. Dry, hot seasons with boggy land favor its development.

Dr. G. F. JENKINS, of Iowa, has noticed that a difference of opinion exists regarding every so-called contagious disease. He has even heard men doubt the contagiousness of scarlet fever. He felt, however, that the profession are the guardians of the people and should defend them in every way. No one ought to stand up and talk against preventive measures.

Dr. SCHAUFFLER, when a boy, witnessed an epidemic of cholera in Constantinople, Turkey, where it raged with terrible violence. The thirst was insatiable and tormenting, but he noticed that those who resolutely refused to drink, though suffering the agonies of the damned, got well, while those who drank water died. He would, therefore, take exception to Professor Flint's advice to allow water to cholera patients.

Dr. J. T. WHITTAKER, of Cincinnati, said that we know that cholera is a disease that multiplies itself in the body and is transmitted to other bodies after the manner of germ diseases. Neither Koch, nor any of his followers, however, have definitely claimed that the comma bacillus is the definite cholera bacillus.

Dr. N. GAY, of Ohio, said: "If you find a man in black collapse and he can still pass a little water, put your ear to his chest. If you can still hear the regular tick-tack of his heart, work with him; there is hope. If, however, either heart-sounds are obscured you need not trouble yourself any further. He is gone."

The second paper was

#### HEMORRHAGIC MALARIAL FEVER,

by JEROME COCHRANE, M.D., of Montgomery, Alabama.

This is a peculiar form of malarial fever which is quite common in some parts of the South. It may be intermittent, remittent, or congestive. A fourth or quasi-continued form may be added, though this form is very rare. Whites alone are affected. Negroes are exempt. It usually attacks persons who suffer from malarial cachexia but may occasionally seize people hitherto well. One attack affords no guaranty against others. The characteristic feature of this disease is the intermittent recurrence of a high-colored port-wine urine. Specimens of this urine were sent to Dr. Sternberg and Professor Martin, of Johns Hopkins University, who reported that the urine contained no blood corpuscles, but was rich in hæmoglobin as shown by spectrum analysis and by the formation of hæmin crystals when the urine was treated with glacial acetic acid, chloride of sodium, and heat. Dr. Webb, of Alabama, however, states that he has observed the blood-cells in the freshly voided urine and thinks they must have become dissolved during the transit of the specimens to the observers mentioned.

In addition to the peculiar urine there occur chills of protracted duration, speedily followed by troublesome bilious vomiting and icteroid discoloration of the eyes and skin. The prostration is excessive, the temperature and pulse are not usually very high

but there may be exceptions. The bowels are usually constipated: the vomitus may vary in color, being yellow, green, black, or even blue.

The black vomit is usually altered bile, but not blood. It is free from the coffee-ground appearance of the black vomit of yellow fever. When this black vomit occurs it is almost always at the beginning of the attack, and is always preceded by red urine. The jaundice appears early and varies in intensity during the attacks. It may grow less toward the end of protracted fatal cases, and sometimes disappears completely after death.

The bloody urine usually shows itself with the initial chill and always in an early stage of the paroxysm. It is profuse at first and then lessens. It may disappear during remissions. Toward the end of fatal cases there is frequently complete suppression of urine. This red urine is highly albuminous and contains granular casts in abundance. As the result of his analysis of 642 cases reported, Dr. Cochrane found that about twenty-five per cent. of all cases died.

Post-mortem appearances are substantially the same as are found in other malarial diseases. The liver is enlarged, congested, and of a dark bronze or slate color. The bile is abundant in the gall, bladder, and intestines. The spleen is enlarged and congested. In addition to these conditions the kidneys are also enlarged and congested.

In the discussion following Dr. Cochrane's paper it was evident that the opinion of the Southern physicians is divided as to whether this is a distinct disease by itself, or merely a modification of ordinary malarial attacks. As to treatment, nearly all the speakers were emphatic in the assertion that quinine is utterly *valueless*. Some even assert that it is injurious in this disease, and increases the hemorrhage from the kidneys. Dr. Cochrane says the broad fact remains that in the treatment of this most dangerous of malarial maladies, quinine, the great malarial remedy, has lost ground, and is still losing ground, in the confidence of the profession. An equally unanimous opinion seemed to prevail that calomel is the drug *par excellence* for this disease. It is given in small doses, and some combine it with soda. One physician recommends orange and lemon juice *ad libitum*. Dr. Cochrane says the chief reliance for the relief of the overburdened kidneys must be sought in the compensating action of the bowels, and especially of the skin.

One remarkable case is reported, where a patient was comatose: the urine reduced to three ounces in twenty-four hours. A hypodermic injection of pilocarpin caused copious sweating in five minutes, and the man gradually recovered his consciousness and got well.

### Recent Literature.

*Orthopædia.* By JAMES KNIGHT, M.D. New York: J. H. Vail & Co., 1884.

*Bodily Deformities and their Treatment.* By HENRY ALBERT REEVE, Philadelphia: P. Blakiston, Son & Co., 1885.

The number of books which have lately appeared on this subject indicate an increasing interest, and

although none of them (including the above-mentioned ones) fill the gap which the medical public finds from the lack of a comprehensive, reliable, thorough, readable work by an expert on the subject, each one seems to approach nearer to the standard.

Of Dr. Knight's book it may be said that the second edition is an improvement on the first, but, to speak frankly, the rate of improvement is such that we would advise the reading public to await the tenth edition, at least, before devoting any time to the work, which is superficial, inaccurate, and, though based on the observation of many and a great variety of cases, resembles the work of a skilful surgeon much as a treatise on banking by a receiving-teller would the dictum of a king of finance.

Mr. Reeves writes from the standpoint of a surgeon who has done many osteotomies, and who has seen work done in a thorough way in certain branches.

The ground covered by the writer is indicated by the title, but he purposely omits the deformities following diseases of the joints, which, with the diseases of the joints, he leaves for other writers.

We cannot think that the author is familiar, practically, with the application of appliances, if we may judge from the pictures, but he has familiarized himself with the literature of the subject and takes a catholic and comprehensive view.

The illustrations are copious and very poor, resembling the eruption which has appeared of late in our American daily newspapers. If we must have such pictures in our medical books, why not drive them to the end of the volume, like Lord Timothy Dexter's punctuation, to be used as the reader's taste prompts, instead of allowing these foci of incompletely developed matter to breed mischief under the protecting tissue of quite sensible text, safe in dispersion from the destructive zeal of the surgeon.

The chapters on lateral curvature, club-foot, rickets, deformities of the upper limb, germ valgum, and osteotomy have much that is readable and instructive.

*Cocaine and its Use in Ophthalmic and General Surgery.* By H. KNAPP, M.D. (Reprinted from the *Archives of Ophthalmology*, December, 1884.) With Supplementary Contributions by Drs. F. H. Bosworth, R. J. Hall, E. L. Keyes, H. Knapp, and William M. Polk. Pp. 87. New York and London: G. P. Putnam's Sons. 1885.

The greater part of the volume is formed by the reprint from the *Archives of Ophthalmology*. This comprises a translation of the original paper of Dr. Koller, and brief abstracts from the numerous communications on the subject which had appeared when the article in the *Archives* was written, together with remarks on the pharmacology of cocaine, its physiological and therapeutical action and special application in ophthalmology. The eagerness with which the new anæsthetic was taken up and its effects observed and recorded is well illustrated here. The reminder of the book is composed of papers on the use of cocaine in otology, in the upper air-passages, in general surgery, in genito-urinary surgery, and in gynecology and obstetrics.

**Medical and Surgical Journal.**

THURSDAY, MAY 14, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by CUPPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM AND COMPANY,

283 WASHINGTON STREET, BOSTON, MASS.

**THE INTERNATIONAL MEDICAL CONGRESS AND THE AMERICAN MEDICAL ASSOCIATION.**

In his address to the American Medical Association at its meeting in Washington last year, its President, Dr. Austin Flint, suggested that the International Medical Congress be invited to meet in this country in 1887. On motion, this portion of the address was referred to a special committee of five. Dr. Billings, of Washington, to be chairman. Subsequently, in accordance with the report of this committee, a second committee of seven was appointed, consisting of Drs. Austin Flint, of New York, G. J. Engelmann, of St. Louis, Christopher Johnson, of Baltimore, I. Minis Hays, of Philadelphia, J. M. Browne, of the Navy, J. S. Billings, of the Army, and H. F. Campbell, of Georgia, President-elect of the Association, to invite, "in behalf of the medical profession in the United States," the International Medical Congress to hold its meeting in 1887 in Washington.

It was further resolved that:—

"The Committee shall elect its own officers, and that, in case the invitation is accepted, it shall proceed to act as an executive committee, with full power to fix the time and to make all necessary and suitable arrangements for the meeting of such Congress, and to solicit funds for this purpose." . . .

"That it shall have power to add to its membership and to perfect its organization, and that to meet the preliminary expenses of printing, postage, etc., the Chairman of this Committee is authorized to draw upon the Treasurer of this Association for an amount not exceeding four hundred dollars."

The invitation was accepted, and the acceptance, as is well-known, was largely due to the influence, the persuasion, and the standing of individual members of this Committee whose names it is scarcely necessary to mention. This Committee, appreciating the value of time, immediately went to work last autumn to complete the organization of committees and officers of Sections, acting as it supposed in its executive capacity. Finally, March

24th, the rules and provisional lists of officers for a preliminary organization of the Ninth International Medical Congress were issued in pamphlet form by Dr. J. S. Billings, Secretary-General, and extensively circulated here and abroad. Dr. Billings then reported what had been so successfully accomplished up to this stage of the Committee's labor to the American Medical Association at New Orleans. Instead of tendering the Committee a vote of thanks through Dr. Billings, the Association was, we will not say led, but stampeded into taking the extraordinary action, recorded in the report of its proceedings, of appointing a new Committee consisting of one member from each State to revise the work of the first Committee, on the absurd ground that the appointment of officers had not been governed by the principle of sectional and local representation. The principle in itself is a poor one applied to this subject, and, moreover, an examination of the list of names shows that all sections of the country are very fairly and worthily represented. It is surely more important that a man should be known to be familiar with the subject he is to direct than that he should come from any particular State, county, or city.

The lists of names of officers as now made out are good ones and cannot easily be improved. The "ins" could be made "outs" and the "outs" "ins"; but that change, with very few exceptions, would only be an improvement to the extent of gratifying some disappointed aspirations for personal notoriety. One thing, however, can certainly be accomplished by the appointment of this new Committee of thirty-eight, namely: a serious delay in the preparations for making the Congress a success, and an infusion of doubt into the minds of the profession in Europe and Great Britain as to the wisdom of coming so far with such uncertainties.

It is reported that this Committee proposes to meet next September, probably in Cincinnati. It may be by that time they will be convinced of the propriety of passing a vote of thanks to the original Committee and adjourning, but even then sufficient mischief to the scheme of the Congress will have been done by the action of the American Medical Association at New Orleans.

We should say that the points to be kept in view by the new Committee of Arrangements when it meets are: the wording of the invitation "in behalf of the medical profession of the United States"; the names of the men upon the Committee of Invitation, without the use of which there would in all probability have been no prospective Congress to squabble over; the subsequent action of these men undertaken in good faith as our *Executive Committee*; the fact that the International Medical Congress has an independent existence with a permanent organization more interested in medical science in the abstract than in local medical politics; that the drawbacks of coming such a distance across the

ocean at much expense, especially to men less accustomed and less able to travel than many Americans, can only be overcome by a united and hearty support of the representative men who have thus far been cordially coöperating with Dr. Billings and the members of the Committee of Invitation; and lastly that the "new code" nonsense had best be allowed to pass into ready oblivion and not be given fictitious importance by further discussion.

It is possible to treat this whole subject too seriously. An editorial in the organ of the American Medical Association, written just after the meeting in Washington, November 29, 1884, of the general committee of twenty-five for the organization of the Congress, shows the official opinion at that time as to the *powers and functions* of the Executive Committee. It says: "A liberal basis of representation for the election of delegates to the Congress by the various medical society organizations in this country was adopted, and the work of the Congress facilitated by the establishment of eighteen Sections. The selection of officers of these several Sections was not completed, but left in the hands of the Executive Committee." etc. etc.

#### PUERPERAL PROPHYLAXIS IN VIENNA.

IX recent numbers of the *Revue Médicale* Dr. Lauwers has described at some length the measures adopted in Vienna to prevent puerperal infection; a brief review of these papers may be of interest in connection with the letter of our Berlin correspondent, who details from personal observation the system of prophylaxis now in vogue in the lying-in wards of the latter city.

It may be said that in Germany, if not indeed throughout the civilized world, the views of Semmelweis on the etiology of puerperal fever are now almost universally accepted. Words have indeed changed since Semmelweis, in 1847, first gave his now famous dictum to the world. "Organic animal matter in a state of decomposition," which he then said was the only cause of puerperal fever, has given place to "microbes" and "bacteria"; but the principles laid down by Semmelweis have outlived the sharp criticisms and bitter opposition of his contemporaries, and form to-day the basis of all intelligent prophylaxis.

The lying-in wards of the Vienna General Hospital, in common with those of many other continental hospitals, are subject to the great disadvantage of contiguity to the medical and surgical wards and the pathological laboratories. This disadvantage increases considerably the difficulty, as well as the necessity, of strict prophylaxis, a fact which should be borne in mind in comparing the results of Vienna with those, for instance, of the Dublin Rotunda. The disadvantage is largely overcome, however, by an admirable system of ventilation

designed by Carl Braun, and by a strict rule forbidding the vaginal touch to all who within twenty-five hours have been in contact with surgical wounds, cadavers, ulcerated cancers of the uterus, sloughing uterine polypi, and fetid vaginal discharge after abortions, etc. Moreover, if the patient at the time of admission to the lying-in room has a temperature above 99.5° F., she is immediately removed to a neighboring room, and no one is allowed to examine her without express authority from the assistant on duty.

For the rest, prophylaxis consists in maintaining the most exquisite neatness of the bed by the use of a plenty of clean linen, and in observing certain rules concerning the disinfection of the hands and instruments, and of the external genitals of the lying-in woman. The hands and forearms are to be cleansed by the vigorous use of soap, nailbrush, and carbolized water; they are then to be plunged for some moments, first into a concentrated solution of permanganate of potash, then into a solution of oxalic acid to remove the stain of the former agent. The end of the examining finger is lubricated with carbolized vaselin, one to thirty. This careful disinfection must be repeated before every examination, whether of the same patient or of others. Instruments are disinfected by immersion in boiling water for half an hour before they are used; and before they are replaced in their cases they are to be thoroughly cleansed and again immersed in the hot water.

Great stress is laid on the proper disinfection of the parturient woman. Toward the end of gestation she is recommended to take a sitzbath from time to time, and when taken in labor she is thoroughly bathed and the external genitals doused with carbolized water (two per cent.) or corrosive sublimate (one to 2,000). When the head is on the perineum the woman assumes the lateral decubitus, and in the intervals of the pains the genitals are freely bathed with the disinfectant solution. After delivery the parts are thoroughly cleansed and disinfected with corrosive sublimate, and a compress wetted in the disinfectant and frequently renewed is placed against the vulva.

It will be seen that there is no essential difference in the prophylaxis of the two cities; in both the end sought after is surgical cleanliness, and this end may be attained by enforcing strict quarantine against those who have been in contact with septic material, and by proper cleanliness of the patient and all that comes in contact with her. The rigid observation of these prophylactic measures in Vienna has reduced the mortality to a minimum; patients no longer die in general of septicæmia and pyæmia, but of such extraordinary complications as eclampsia, placenta prævia, and other accidents beyond the power of antiseptic methods to prevent. Thus at last, after nearly forty years, have the labors of Semmelweis borne fruit in the place whence

he first proclaimed the significance of puerperal fever, and where he exemplified the methods by which it could be prevented.<sup>1</sup>

### THE ARTIFICIAL PONDS IN THE NEW YORK CENTRAL PARK.

THERE is a breeze, and not a very salubrious one, just now in the community over the unhealthy condition of the lakes and ponds in Central Park, which are said in reality to be little better than enormous cesspools. Their original construction was a serious blunder, and, apparently, nothing of any moment has ever been done to remedy the evils necessarily incident to their faulty sanitary provisions. Of late their condition has been particularly bad because, on account of the comparative scarcity of Croton water, the Commissioner of Public Works has refused to allow any of the latter to flow into them, and the water which they contain has been supplied from surface drainage. This sends into these basins a vast amount of impurity, and one source of this is the numerous water-closets in the park. In addition, the ponds are not drained because the sewerage in the park is of a different character from that in the surrounding part of the city. In regard to the large pond near the entrance at Fifth Avenue and Fifty-ninth Street, which, from its proximity to the street, is more apt than any of the others to affect the houses of the neighborhood with its dangerous emanations, the president of the Park Commission says that the bottom is several feet lower than the sewer with which it is connected, so that, under the circumstances, there must constantly be accumulating in it a large amount of filth drained from the roadways and closets. The stagnation appearance of the water in this pond and the stench which frequently arises from it are simply loathsome, and it is not to be wondered at that there has been a large amount of illness among the police force employed in the park. The commissioners have just sent to the mayor a report of an investigation by them of the condition of the ponds and the sources of the contamination of the water, and it is probable that radical measures for the correction of the above, which has so long disgraced the great pleasure resort of the people, will be undertaken at once.

### THE LIMITATIONS OF QUININE IN MALARIA.

ONE of the most important points brought out at the recent meeting of the American Medical Association at New Orleans was the delimitation, so to

speak, of the boundaries of quinine. The terms, the South, malaria, and quinine, have become to us synonyms, and excite in our minds the picture of a thin, sunken-eyed, yellow-visaged, shining wretch, with a bitter taste on his tongue and a roaring in his ears. And, indeed, malaria is the problem of the South. Dr. Jones, of the Health Commission of New Orleans, declares that malaria is the scourge of the Mississippi Valley and that it slays more victims annually than any other disease, not excepting consumption and yellow-fever epidemics.

Now it appears that there is one peculiar form of hæmorrhagic malaria, as described in our report of the proceedings. This is a very deadly form of the disease and kills fifty per cent. of its victims. It is characterized by severe congestion of the kidneys and the escape of blood in the urine. The prostration and suffering are extreme and rapid, and it would seem as if the great anti-malarial quinine was needed here more urgently than under any other conditions, and yet it is just here that its limitations are drawn.

The testimony of the Southern fraternity was almost unanimous that quinine in large or small doses has no curative effect whatever upon this disease. It may control the temperature in some cases, but as this disease is not usually accompanied by high fever a mere antipyretic is not indicated. So far as the chills are concerned the quinine is powerless and it does actual harm by increasing the congestion of the kidneys and producing greater hæmorrhage.

Free use of calomel has given the best results in this disease, and all, in New Orleans, testified to their satisfaction with that drug. It seems like a paradox to think of a Southern physician treating a case of malaria without quinine, but those of us who had experience in our Marine-Hospital Service will recall not a few cases of salivation among sailors coming from Southern ports where there was no reason to doubt that the condition was induced to relieve the patient of malaria and not of syphilis.

### MEDICAL NOTES.

—Dr. Squibb, in *The Ephemeric*, remarks that the official aqua creasoti, or creasote water, a simple one per cent. solution of wood creasote in water, is, like similar solutions of carbolic acid and of cresol, a most effective local anæsthetic and topical dressing to burns and scalds. It is no better than the solutions of carbolic acid, or of coal-tar creasote, for this purpose, but it is quite as good, so that whichever is most accessible or most convenient may be used. This creasote water, as made by the above formula, — or diluted with an equal volume of water, or with more water for delicate surfaces in women and children, — and applied by means of a single thickness of thin muslin or worn-out cotton or linen, such as handkerchief stuff, and the appli-

<sup>1</sup> From the year 1811 to 1817 there died in Vienna about one woman in ten of puerperal fever. In 1817 Semmelweis became assistant in the first obstetric clinic; at the end of 1846 he had lost only one woman in eighty. In the month of March, 1848, he lost only one in 276, and not one in 261 in the month of August. In 1849 he accepted the chair of Obstetrics in Pesth, and was succeeded in Vienna by Carl Braun.

cation renewed from time to time, as the return of pain requires it,—will relieve the pain of burns and scalds in five to ten minutes and will maintain the relief as long as the applications are properly renewed or until the painful stage is over. In view of the importance of this preparation for the special use of treating burns, Dr. Squibb expresses surprise at the general adhesion to the old and comparatively useless dressings such as carron oil, white lead ground in oil, flour, liniments, etc., or the newer application of bicarbonate of sodium.

—In his recent Lettsomian lectures on Indigestion, Dr. Lauder Brunton declares acid fruit to be indigestible and apt to cause intestinal irritation. He believes sour wines to be peculiarly liable to cause indigestion, and, when taken regularly, to cause gastric catarrh. The tannin in tea interferes very considerably with the digestion of fresh meat, though such is not the case with dried meat, such as ham or tongue. Tea at breakfast is not apt to produce gastric disorders, but afternoon teas are pronounced bad. Infusions of tea should be “light drawn” and drained from the leaves before serving, as by this means only a small portion of the tannin becomes dissolved in it.

—The oldest medical student on record may be safely claimed to be one who has recently taken a degree at the University of Berlin at the age of 71. He had previously been a missionary in Africa and has returned thither, where he apparently believes practice will be better than preaching.

—A correspondent of the *British Medical Journal* relates an instance of hereditary transmission of Dupuytren's contraction. The patient, twenty-three years of age, has had, from birth, the little finger of his right hand contracted; it is flexed toward the palm of the second and third phalangeal joints, and the whole finger deviates somewhat to the radial side of the hand. On the whole, it is a typical example of Dupuytren's contraction. The patient's maternal grandfather and his mother's brother both have the same finger of the same hand contracted in a similar way; and in both these cases the contraction is said to have existed since birth. The patient has one brother and four sisters living, none of whom exhibit any finger-abnormality. There is no family history of either gout or rheumatism.

—Dr. Koch tells the following story about the origin of his celebrated cultivative experiments. He had been, like many others, trying various kinds of decoctions and infusions, when walking along the street one day he noticed a potato covered with a fungous growth, and it occurred to him that disease germs might thrive equally well on the same nutriment. This was the beginning of his wonderful series of dry cultivated experiments, and thus Professor Whittaker expressed it at New Orleans: “The potato was to Koch what the apple was to Newton.”

—Dr. Stelwagon, in a recent issue of the *Medical News*, calls attention to iodide of potassium as a useful drug for internal administration in the treatment of eczema. It is especially adapted to persons in good general health, rather than to the broken-down or the dyspeptic.

—A curious but important case, says the *British Medical Journal*, in which smallpox infection was conveyed in a letter, is recorded by Mr. Karkeek, in his recent report on the sanitary condition of St. Marychurch. On March 1st, last year, a case of smallpox was reported to him in the person of a domestic servant, who had seen no one ill or recovering from smallpox, and who had not been out of the town for months. Moreover, no case of the disease had occurred in St. Marychurch or Torquay for years. On inquiry, it was found that the infected person had received letters from her sister, an inmate of the West Bromwich Smallpox Hospital, “who had unfortunately sent the germ of the disease in her letter.” The case was at once removed to the Torquay Sanitarium, and the only person in the household who became ill was the recipient and reader of the letters.

—“You are doing nicely,” said the doctor encouragingly to an old darkey patient; “I will call again to-morrow, and will leave you this prescription now to save you from pain in the interim.” Then he went out. “Da's er 'scription dat de doctah lef,” said the patient feebly to his wife, “an' I wan's yo' ter go to de drug sto' an' git it filled. Tell de drug sto' man dat it's fo' my interim, an' be sho' an' ax him ef Ise ter take it eternally, or jess rub it on de outside, an' ef so, wha'?”

—A very remarkable case is given in the *London Medical Record* April 15th, quoted from the *Wiener Med. Blätter* of May 29, 1884. A young woman, who had previously been quite healthy, with the exception of a rheumatic attack which had left some cardiac weakness behind it, had suffered since the spring of 1882 from symptoms of gastro-intestinal catarrh, with various other anomalous symptoms, for which she was admitted several times into the hospital at Upsala. The appearance of boils on the arms led to her transfer to the surgical wards, in the summer of 1883, where one of them was opened and a needle extracted. Needles being found in boils on other parts of the body, the patient confessed that in May, 1881, she had swallowed, at intervals extending over two weeks, five and a half packets of needles, each containing twenty-five, with the intention of destroying herself. At first she felt no inconvenience, but after a few weeks pains came on in various parts of the body, with constipation and other unpleasant symptoms. So far as she knew, no needles had been passed with the feces. After repeated operations, some under chloroform, one hundred and ten needles in all were removed from the body of the patient.

## NEW YORK.

— During the first four months of the present year the deaths in New York numbered 12,527, as against 10,763 for the same period in 1884. Last year during the same four months there were 1,761 deaths from phthisis, 571 from bronchitis, and 1,339 from pneumonia, making a total of 3,674. During the same period this year there were 1,911 deaths from phthisis, 756 from bronchitis, and 2,051 from pneumonia, a total of 4,721; the increase of over one thousand being principally due to the large increase in deaths from pneumonia.

— The closing exercises of the Training-School for Nurses, of the New York Hospital, took place at that institution, April 27th. There were six graduates, and Dr. George L. Peabody made the address to them.

— The third annual meeting of the Faculty of the New York Post-Graduate Medical School was held May 5th, when Dr. D. B. St. John Roosa was re-elected President, and Dr. F. R. Sturgis, Secretary. The annual report of the secretary showed that 133 graduates in medicine had attended the lectures of the school during the past year.

— In accordance with recommendations of the Trustees of the Binghampton State Asylum for the Chronic Insane, the State Board of Charities and the State Commissioners in Lunacy have decided to provide tent accommodations for the temporary shelter of two hundred patients during the coming summer; the measure being adopted in view of the crowded condition of the asylum, and on account of the benefit which it is believed will be derived by the patients from the outdoor life.

— A short time since the Board of Health sent a communication to Gen. Alexander S. Webb, President of the Sanitary Aid Society, in reply to certain strictures which had been made in regard to the work of the board, in which it is stated that during the three months ending March 31, 1885, the fifteen sanitary inspectors in its employ inspected 11,603 premises, including 7,598 tenement-houses, and that they found 13,083 causes of complaint, among which were 3,001 waste-pipes and drains, 3,631 vaults and closets, and 769 cellars and basements. Over one thousand privy vaults were ordered removed. Having mentioned that a systematic house-to-house visitation among the tenement population is now in progress, and given further details of the work of the sanitary inspectors, as well as of the police force attached to the Health Department, the report goes on to say: "The foregoing statement, which does not represent the entire work of the department, is sufficient to demonstrate how fully the duties enjoined upon this board have been performed, and that the officers and the means it has been enabled by its regular appropriations to employ, have been thoroughly and diligently used." The Sanitary Aid Society has had

presented to the Legislature a bill which provides that the New York Board of Health may appoint and commission twenty additional sanitary inspectors, who shall be sanitary engineers, and that these twenty additional sanitary inspectors, and, at least, fifteen officers and men, detailed from the police force to the service of the Health Department, shall be assigned exclusively to the work of inspection of, and improving the laws and regulations relating to, tenement and lodging houses. One of the important features of the work of the Aid Society is the fitting up of model lodging-houses, which provide comfortable and healthful accommodations to the poor at the lowest possible rates; and one of them has just been opened in the Tenth Ward.

## Correspondence.

## LETTER FROM BERLIN.

BERLIN, April 9, 1885.

MR. EDITOR. — The first fact which a stranger notices in Berlin is its greatness and splendor, but an observing mind is not less impressed with its cleanliness. Everywhere, in street and square, in court and alley, the same absence of dirt or garbage. The change from New York and Hoboken to Bremen and Berlin in this respect is wonderful. The cause is not far to seek; it is the thorough acceptance by the professional and the official mind of the modern views as to the causes of endemic diseases. It is not an æsthetic yearning after neatness which causes the present condition of Berlin: it is a deliberate attempt to stamp out typhoid, and to keep away cholera, by patient, careful, continuous work and watchfulness, attacking disease present, and preparing for threatened epidemic invasion, in the same spirit, and with the same pains, that has led to success in domestic struggles and foreign wars.

On visiting the hospitals, the same cleanliness is even more remarkable, and is especially grateful to one who saw something of Continental surgery some fifteen years ago. The whole theory of sepsis, as caused by germs, is accepted by every one who is connected with the hospitals, although I am told that there are conservatives among the older professional leaders who, although silent, are unconvinced.

The first subject which I have taken pains to investigate, as of peculiar interest to your readers, in view of recent rather animated discussions in the Suffolk District Society is the question of the use of vaginal injections after normal labors.

I find that they are *not* so used in the lying-in hospitals, either here or in Munich, or as far as is known in any other of the institutions of repute in Germany. The two great institutions here are under the charge of Professor Schroeder and Professor Gussow; those of Munich, under Professors Winkel and Anman, the latter of whom I have met here. All testify to the same fact; that formerly they used vaginal injections after normal labors, but that since the perfection of prophylactic treatment *ante partum*, and especially since the introduction of corrosive sublimate, they have found such injections unnecessary. As they were sometimes injurious, they are now only used in cases where some special indications, as fever or foul lochia, call for them.

Professor Anman assured me that he treated, without injections, five hundred consecutive cases of labor in the Munich hospital recently, with only one death, and that was from pneumonia acquired before entrance.

In the lying-in department of the Royal Charité,

which is under the direction of Professor Gussow, and under the immediate management at present of Dr. Rumpf for cases in the house and Dr. Wyder for cases attended at home, there are some three thousand deliveries yearly. These gentlemen, who have treated me with distinguished courtesy, assure me that having formerly used vaginal injections in all cases they have now abandoned them, unless in special cases for special reasons—as above, and for the last six weeks or two months, since they have not used them, they have every reason to be well satisfied with the change.

Certainly, in repeated visits to the lying-in wards, I fail to find anything like the usual proportion of cases of febrile character. The same is true of Professor Schroeder's cases.

It may not be uninteresting to state just what the present system of prophylaxis is as I have seen it, although I may be repeating what your readers have already seen. After a bath, and scrubbing of the body and especially of the genitals with soap and water, the vagina is well and thoroughly doused with a solution of corrosive sublimate in water one to 5,000, and the external parts and ostium vaginae are washed with a solution of the same one to 1,000; whenever during labor there are repeated digital examinations, the vaginal douche one to 5,000 is used again. Toward the end the vulva is well anointed with corrosive sublimate in glycerin one to 1,000. The woman is delivered on her side, as in Boston, the English fashion having been lately introduced at the *Charité* by Professor Gussow. The cord is not tied for some minutes, until the pulsations cease or grow faint. The placenta, if not expelled naturally, is squeezed out by Crede's method; ergot is then given, and the vagina is well washed out with the one to 5,000 solution; if there has been any operation the uterus is also washed out with the same solution. Then the vulva is washed and soused with the one to 1,000 solution.

After that there is no more vaginal douche, and no need of it; external cleanliness, and daily washing the vulva with one to 1,000 sublimate solution suffices.

The most scrupulous care, however, is taken to prevent infection by the doctors or nurses during delivery. Everywhere in the ward and in the lying-in room are abundant facilities for handwashing, which is not a simple form, but a real scrubbing of hands and arms up to the elbow. This is done most thoroughly before and after examinations *per vaginam*, and in deliveries the hand is always put into the one to 1,000 sublimate solution before making an examination. It is then not dried but oiled while wet and so introduced. *Finis corporali optus.*

Any one who remembers the way things were done years ago in lying-in wards must concede that the improvement of results must be credited to the change of practice. I have only written of the custom in hospitals, but in private practice the cases are managed on the same general lines.

Passing from the mother to the child, I have only to report that Crede's procedure of instilling a drop of two per cent. solution of argent. nit. into the eyes of newborn children is still in force, and in the highest esteem. The eyes are immediately washed off with cold water. Ophthalmia neonatorum has disappeared from the wards. In the gynecological departments of the hospitals, which are under the same professional-superior direction as the lying-in wards, the same scrupulous care prevails. Everywhere soap and water and sublimate, and sublimate and water and soap, and *duo optus.*

The great courtesy of Dr. Bangsarow, staff-surgeon in charge, has enabled me to watch the procedure thoroughly. Each woman who comes into the examining-room from the wards brings her special vaginal-tube, and before and after the treatment is well doused with one to 5,000 sublimate solution, with moreover much and ceremonious washing of hands and

instruments between each case. In operations, all the principles of antiseptic surgery are most thoroughly carried out. Martin, Schroeder, and Gussow all use the carbolic spray in laparotomy, but not directed on the wound.

The room is first thoroughly disinfected by carbolic spray or burning sulphur for twelve hours and the spray is played in the air, making a fine mist heavily charged with the acid. Martin requires all present to take a bath just before the operation, to wear clothes not worn in hospital rooms and clean underclothing throughout. Schroeder has similar rules not quite so stringent, but of course no one can come who has the remotest connection with pathological work or septic diseases. There is a *septic* assistant at Schroeder's hospital, who takes care of cases which come in that condition, and makes cultivations of bacteria, etc.

With these precautions the results of gynecological operations are wonderful, and it is astonishing to see what an amount of scraping and cutting and sewing the uterus will bear without febrile reaction or perimetritic inflammation.

Of course much that is done, especially in Martin's hospital, strikes a stranger as reckless, not to say unwarrantable. But after watching the results of the operations and studying the temperature charts, one must concede that they practically all turn out well; a whole series of operations capital and otherwise with only one fatal case (in a very complicated myotomy), and in the rest hardly ever an elevation of temperature of more than one or two degrees, must convince the most incredulous of the value of the method of thorough antiseptic treatment as practised by Martin.

I will mention a case that seemed to me to be a pretty severe crucial test.

A woman appeared with an obscure tumor in the right hypogastrium, with frequent bleeding, and no interruption of menstruation. The sound showed the uterus to be normal size, or nearly so; it was scraped out, but the bleeding did not stop. At a second examination under chloroform to clear up the doubts raised by the fact that the membrane scraped out showed the characters of pregnancy, it was found that it was a case of double uterus with a dead fetus. Without delay, the long curette goes into the other side, then hooked forceps, but the fetus is soft and only parts come away; then the uterine artery of that side is tied, using a curved needle, the cervix is slit up on that side, the fetus is extracted in pieces, the placenta scraped off and extracted; then about a drachm of pure liquor ferri chloridi is injected, and then the cavity is well washed out with one to 5,000 sublimate solution, the cervix is sewed up, the ligature removed from the artery, the vagina again washed out, and the woman put to bed. Of course she had been well bathed and washed before the operation, which, like all Martin's operations began with a thorough irrigation of the vagina, by the one to 5,000 solution and was continued under a continuous flow of the same solution from an irrigator.

The patient lies on the back, the perineum is drawn down with a spoon speculum, and the uterus is drawn out and held by forceps; the same assistant who holds these forceps holds with them in his hand the nozzle of the irrigator, which always keeps the wound, or the uterus and vagina, bathed in the one to 5,000 solution, which for long operations is warmed and diluted one half.

The woman operated on, as above, seemed to have rather a poor chance of recovery, but sure enough in a few days I saw her in full convalescence and she never had any fever or serious symptom.

I have mentioned this case at some length because it is rare, and rather characteristic of Martin's way of proceeding, and shows at the same time that his confidence in himself and his method is not in vain.

The method, however, seems to require the discipline

and resources of a very well-regulated hospital, as well as the hand of a master. An operation such as I have described, or even one of less importance, is done with the assistance of Dr. Duvelin and three trained assistants, and two expert nurses, and the whole preparation and care of patient, rooms, and instruments require an amount of careful and intelligent supervision very difficult to obtain even here. In fact, Martin divides his statistics of cases into two groups, those up to within the last few years, and those of the later date, the dividing-point being the time when under the unwearied and vigilant care of

his present matron, Frau Horn, he was able to make his antiseptic treatment thorough and perfect at all points. The advent of corrosive sublimate, as a germicide, has been indeed a blessing as far as expense goes; for the same money 100,000 times as much disinfectant solution can be prepared as with carbolic acid, and of course this does much to popularize the methods of thorough antiseptics, which are destined to have so vast and far-reaching influence, not only on surgery and obstetrics, but in so many and varied fields of public sanitation and human welfare.

Truly yours, E. W. Cushing, M.D.

## REPORTED MORTALITY FOR THE WEEK ENDING MAY 2, 1885.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 2,247; under five years of age 597; principal infectious diseases (smallpox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhoeal diseases) 348, consumption 148, lung diseases 287, diphtheria and croup 107, diarrhoeal diseases 77, scarlet fever 12, measles 31, malarial fevers 21, whooping-cough 20, erysipelas 17, typhoid fever 17, cerebro-spinal meningitis 10, puerperal fever three. From measles, New York 17, Brooklyn six, Philadelphia six, and Boston four each, New Bedford, Chelsea, and Gloucester one each. From malarial fevers, New York eight, Brooklyn and New Orleans five each, Baltimore two, District of Columbia one. From whooping-cough, New York seven, Philadelphia five, Brooklyn four, New Orleans, Providence, and Nashville one each. From erysipelas, New York five, Philadelphia four, Boston and Baltimore two each, Providence, Lawrence, and Springfield one each. From typhoid fever, New York and Philadelphia five each, Baltimore three, Boston, Charleston, Springfield, and New Bedford one each. From cerebro-spinal meningitis, New York, Worcester, and Fall River two each, Philadelphia, Baltimore, District of Columbia, and Brockton one each. From puerperal fever, New York, District of Columbia, and Charleston one each.

Cases reported in Boston: measles 89, scarlet fever 30, diphtheria 25, and typhoid fever eight.

In 110 cities and towns of Massachusetts, with an estimated population of 1,326,883 (estimated population of the State 1,355,101), the total death-rate for the week was 19.00, against 19.73 and 20.15 for the two preceding weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,906,106, for the week ending April 18th the death-rate was 23.2. Deaths reported 3,966; infants under one year of age 899; acute diseases of the respiratory organs (London) 419, measles 199, whooping-cough 109, fever 12, scarlet fever 38, diphtheria 20, diarrhoea 29, smallpox (London 11, Liverpool and Manchester two each, Sunderland one) 16. The death-rates ranged from 16.5 in Derby to 25.7 in Plymouth; Birkenhead 17.9; Birmingham 21.2; Blackburn 22.7; Bradford 21.3; Hull 16.2; Leeds 23.8; Leicester 22.2; Liverpool 25.2; London 21.8; Manchester 35.2; Nottingham 15.8; Sheffield 25.1; Sunderland 32.9. In Edinburgh 18.3; Glasgow 27.2; Dublin 33.7.

In the Swiss towns for the week ending April 18th there were 41 deaths from consumption, lung diseases 11, diarrhoeal diseases 10, smallpox eight, whooping-cough four, diphtheria and croup three, scarlet fever two, measles one.

The death-rates were: at Geneva 19.2; Zurich 15.5; Basle 37.0.

The meteorological record for the week ending May 2d, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending Saturday, May 2, 1885.	Barom-eter.	Thermometer.				Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MAY 2, 1885, TO MAY 8, 1885.

**BILL, JOS. H.,** major and surgeon. Ordered for duty as member of Army Medical Examining Board, New York City, N. Y.

**SPENCER, WILLIAM G.,** captain and assistant surgeon. From Department of the East to Department of Dakota.

**BRECHEMIN, LOUIS,** captain and assistant surgeon. From Department of the East to Department of the Platte.

**DAVIS, WILLIAM B.,** captain and assistant surgeon. From Department of Dakota to Department of the East, S. O. 100, A. G. O., May 2, 1885.

**STERNBERG, GEORGE M.,** major and surgeon. Detailed to attend, as a delegate on the part of the Government of the United States, the Sanitary Conference to be held at Rome, Italy, on May 15, 1885. S. O. 103, A. G. O., May 6, 1885.

**COWDREY, STEVENS G.,** captain and assistant surgeon. Assigned to duty as post surgeon, Fort Bliss, Texas. S. O. 65, Department of Missouri, May 2, 1885.

**ARTHUR, WILLIAM H.,** first lieutenant and assistant surgeon. Assigned to duty at Fort Niagara, N. Y. S. O. 89, Department of the East, April 28, 1885.

**WYETH, M. C.,** first lieutenant and assistant surgeon. Ordered for temporary duty at Fort Wadsworth, New York Harbor. S. O. 95, Department of the East, May 6, 1885.

#### SOCIETY NOTICES.

**SUFFOLK DISTRICT MEDICAL SOCIETY.** *Obstetric and Gynecological Section.*—The last meeting of this Section for the season will be held at 19 Boylston Place, on Wednesday, May 20, 1885, at 7.45 P. M. Dr. R. A. Kingman will read a paper on "Anæsthetics in Normal Childbirth." Dr. J. P. Reynolds will make some remarks on the "Legitimate Prevention of Pregnancy." Gentlemen are invited to bring specimens to exhibit before the Section. Cigars and beer will be served after the meeting.

**JAMES R. CHADWICK, M.D.,** Chairman.  
**ROBERT B. DIXON, M.D.,** Secretary.

#### DEATHS.

**DIED.**—In Boston, May 6, 1885, Joshua Brackett Treadwell, M.D., M.M.S.S., aged forty-four years.

#### BOOKS AND PAMPHLETS RECEIVED.

Transactions of the Obstetrical Society of London, Vol. XXVI., for the Year 1884. With a List of Officers, Fellows, etc. London: Longman, Green & Co., 1885.

Clinical studies on Diseases of the Eye, including those of the Conjunctiva, Cornea, Sclerotic, Iris, and Vitreous Body. By Dr. Ferdinand Ritter von Arlt, Professor of Ophthalmology in Vienna. Translated by Lyman Ward, M.D. Philadelphia: P. Blakiston, Son & Co., 1885.

Many Drugs—Few Remedies. By George T. Welch, M.D. (Reprint from Medical Record, 1885.)

What to do in Cases of Poisoning. By William Murrell, M.D., F.R.C.P. Fourth edition. London: H. K. Lewis, 1884.

How to Drain a House. Practical Information for Householders. By George A. Waring, Jr., M. Inst. C. E. New York: Henry Holt & Co., 1885.

Ovariotomy. By James B. Hunter, M.D. (Reprint from New York Medical Journal, June 7, 1884.)

Fifty Cases of Abdominal Section, with Remarks on Laparotomy. By James B. Hunter, M.D. (Reprint from New York Medical Journal, April 4, 1885.)

Prescribing Alcohols. By John Blackmer, M.D. New York, 1885.

Disinfection and Disinfectants. Preliminary Report made by the Committee on Disinfectants of the American Public Health Association.

The Invalid's Test-tray. By Susan Anna Brown, author of Forty Puddings, etc. Boston: J. R. Osgood & Co., 1885.

A Treatise on Abdominal Palpation as applied to Obstetrics and Version by External Manipulations. By A. Pinard, Associate Professor, Faculty of Medicine of Paris, etc. Translated by L. E. Neale, M.D. New York: J. H. Vall & Co., 1885.

Medical Jurisprudence in Divorce. By Carl H. von Klein, A.M., M.D., Dayton, Ohio. (Reprint from the Journal of the American Medical Association, February 14, 1885.)

Modern Therapeutics of the Diseases of Children, with Observations on the Hygiene of Infancy. By Joseph E. Edwards, M.D. Philadelphia: D. G. Brinton, 1885.

Plucking Crows in School Gradients and the celebration of Arbor Day. Department of the Interior. Bureau of Education, Washington, 1885.

Circulars of Information of the Bureau of Education. No. 1. 1885. City School Systems in the United States. By John D. Philbrick, L.L.D., Washington, 1885.

A Plea for Epistiotomy. By W. P. Manton, M.D. (Harvard.) (Reprint from American Journal of Obstetrics, No. 3, 1885.)

Quarterly Station-List of Officers of the Medical Department and Hospital Stewards U. S. Army, April 1, 1885.

The Treatment of Mastitis by Bandaging and Rest. By Philander A. Harris, M.D., Paterson, N. J. (With Cuts.) (Reprint from American Journal of Obstetrics.) New York: William Wood & Co., 1885.

Injuries of the Spine and Spinal Cord without apparent Mechanical Lesion, and Nervous Shock, in their Surgical and Medical Aspects. By Herbert W. Page, M.A., M.C. (Cambridge.) Second Edition. Philadelphia: P. Blakiston, Son & Co., 1885.

Dr. Seguin's Metric Prescription Book. New York and London: G. P. Putnam's Sons, 1885.

Neuralgia and the Diseases that resemble it. By Francis E. Austin, M.D., London. New York and London: G. P. Putnam's Sons, The Knickerbocker Press, 1885.

Fourteenth Annual Report of the Managers of the Buffalo State Assn. for the Income for the Year 1884. Transmitted to the Legislature January 15, 1885. Albany, 1885.

Thirty-ninth Annual Announcement of Sterling Medical College, together with Catalogue for 1885-86. Columbus, Ohio, 1885.

Handbook of Diseases of the Skin. Edited by H. v. Zeisler, M.D., Professor of Clinical Medicine in Munich. Illustrated. New York: William Wood & Co., 1885.

Normal Standard of Physiology. By Nathan Allen, M.D.

Twelfth Annual Report of the Board of Health of the City of New Haven, 1884.

Vorträge herausgegeben vom Deutschen geodätisch-wissenschaftlichen Verein vom New York. No. 10. Volksmedizin. Dr. A. Jacobi.

SOME NON-VALVULAR DISEASES OF THE HEART.<sup>1</sup>

BY ROBERT T. EDDES, M.D.

THE valvular diseases of the heart are naturally those to which the student turns with most interest during his period of instruction, and to which the practitioner is most likely to direct his efforts in diagnosis; the reason in each case being equally obvious, that is, the nicety at which diagnosis has arrived and the accuracy with which effects can be traced to distinct mechanical causes. The satisfaction is not unreasonable with which one points out within a finger's breadth the exact location of the little fibroid mass which is filling the limbs and the great cavities with water, congesting the internal organs, and disturbing, from lack of vital fluid, the nutrition of the whole body, especially if this knowledge can be made to serve, even if not for cure, at least for relief. Let us hope that the physician may always show himself a wise man, as well as a skilful diagnostician, when nature has mercifully concealed some of her imperfect handiwork, and not betray her secret prematurely to cause mental anguish long years before her defects have of themselves come to light.

My object is to call attention to some other affections of the heart which excite less interest, for the reason that they are less well understood and less easily diagnosed. I can add little or nothing to our present knowledge, but sometimes the mere stirring up of a subject may draw out new facts and tend to a clearer understanding, even if it be only to recognize the limits of our knowledge.

The function of the heart is not to make rhythmical sounds for the study of the physiologist or abnormal ones for the delight of the clinician, but to carry the blood all over the body; and if it does this perfectly we may neglect, within certain limits, the amount of noise which it makes in doing it.

The heart is often spoken of as a pump. As such we study its valves and orifices. Let us, however, call it a pump with a man to work it, and then we must consider not only the valves but the muscles and nerves of the laborer who keeps it in action.

The nervous system of the heart has been much studied from an anatomical, and even more from a physiological, point of view, and these studies are undoubtedly to be of greater value than heretofore, when something more of clinical observation and of pathological anatomy have been added. At present the amount of pathological knowledge based on actual dissection of this system is small. It is so, for the very obvious reasons of the great amount of labor and skill which must be expended in the investigation of cases of which only a small fraction would make any return in positive facts.

I shall not make any attempt to show the present state of our knowledge on these points of anatomy, except in a very elementary way, and for this purpose exhibit this copy of a plate from Dr. Byron Bramwell's new book and a dissection showing the situation of the cardiac ganglia, and also the extent

to which the great vessels and plexuses are enwrapped in the pericardium.

A recent writer, Michel Peter,<sup>2</sup> a pupil of Tronseau and editor of his works, has endeavored to bring into more prominence the part which the cardiac plexuses may play in some diseases in their neighborhood and under their control, especially pericarditis and aortitis, and to show that the symptoms are not all due to mechanical interference with the heart's action, but in a great measure to irritation of its complicated innervation. The relations of the pericardium to the base of the aorta and pulmonary artery, upon which are situated the chief cardiac plexuses, are so intimate that inflammation of that membrane may affect not only the distribution of the nerves, as happens of course almost anywhere in the body, but their secondary or local centres; and Peter lays great stress upon the pain communicated by direct contiguity to these ganglia, and to the phrenic nerves in many cases of pericarditis, as an important element, not only in the distress, but also in the severity and danger of the disease.

I quote at some length his own words:—

“But the pericardium is in relation not only with the great vessels; it is found in the closest proximity with the cardiac plexus which, as is well known, is situated upon the aorta and pulmonary artery; the ganglion of Wrisberg of this plexus being found in the angle of junction of the two vessels.

“Thus, I repeat it designedly, the visceral pericardium is directly in relation with the cardiac plexus, a very delicate connective tissue attaching the nerves of the plexus to the pericardium as well as to the external coat of the aorta and pulmonary artery, and it follows from these relations of the pericardium, hitherto entirely mistaken by the anatomists as well as the pathologists, that there may be serious consequences when the pericarditis having become generalized from the parietal layer to its aortico-pulmonary visceral layer, the process of inflammation has invaded the neurilemma of the nerves and the nerves themselves. In fact, from the transmission of the inflammation to the six branches of the sympathetic and six branches of the pneumogastric which may be concerned, there results a series of phenomena which may, and do, give to acute, and even to chronic, pericarditis a special and complex symptomatic physiognomy and sometimes a frightful severity. The careful study of these relations and the physiologico-pathological consequences to be drawn from them, as one might say, *a priori*, are able to clear up to a singular degree the somewhat obscure symptoms of pericarditis as it is described by otherwise careful writers (p.64).

“My own studies, not less than a careful and respectful analysis of the works of writers whose researches I appreciate without always accepting their conclusions, permit me to affirm that the malignant syncopal forms of pericarditis may be referred, not to muscular, but to nervous, lesion, and the study which we have made of the anatomical relations indicate in advance upon which of these nerves the inflammation acts.

“In a word, according to its seat, pericarditis may

<sup>1</sup>Tratte clinique et pratique de maladies du coeur. Par Michel Peter. Paris, 1885.

<sup>2</sup>Read before the Suffolk District Medical Society, April 25, 1885.

provoke a neuritis either of the phrenic or of the cardiac nerves.

"I have in fact twice found a lesion of the phrenic nerves, as well as some of the branches of the cardiac plexus, in cases of pericarditis originally acute and having passed into the chronic state. The neurilemma was thickened and vascularized, very adherent to the pericardium and to the false membranes which covered it. The nervous tubes were here and there strangulated and deprived of myelin at the point of strangulation" (p. 78).

In speaking of Dr. Sibson's article on pericarditis in Reynolds's System of Medicine, he says: "The learned English physician attributes, with me, to the irritation and the inflammation of the nerves of the cardiac plexus, as well as to those of the heart itself, a part of the pains of pericarditis and a series of reflex acts, particularly of the vasomotors, whence possibly the paleness of the face by vascular contraction. Sibson goes further: he refers to an inverse phenomenon, although also of the reflex kind, that is, vascular dilatation, the redness of the face alternating with paleness; and I am of his opinion. What he says of the face he says also of the heart and the pulse; and the community of ideas between us can be here seen.

"The many and important nerves situated at the surface of the heart and great vessels may be more or less involved in the inflammation affecting those parts in pericarditis. When we consider that electrical or other excitation of the vagus retards the contractions of the heart, and if it is strong enough, arrests the organ in diastole, and in the dog lessens arterial pressure; while division of the vagi produces acceleration of the contractions of the heart, and in the dog increased arterial pressure; that the lower cervical ganglion of the sympathetic exercises an accelerating influence, not always in action, on the contractions of the heart; and that in the frog, the ganglion cells contained in the heart are the springs of its automatic movement and that the surface of the heart is rich in nerves connected with the vagi, the sympathetic, and the intrinsic ganglia of the heart, and that those nerves are therefore locally affected by the inflammation in pericarditis,—we must, I consider, conclude that this affection exercises in such cases an important influence, either to stimulate or to injure those nerves, and so to accelerate or retard the contractions of the heart, to excite, or, more frequently, depress, the powers of the organ, or to increase or diminish arterial pressure."<sup>3</sup>

The following case seems to me to show something of the importance of these considerations quite as strongly as those which the author brings forward himself, since it deals not with an extensive pericarditis or one which, having done much mischief by direct action on the heart, finally invades a more distant region whence its nervous influence may be felt, but with a very limited affection which simulated a valvular lesion and undoubtedly did actually give rise to some relative valvular insufficiency, while itself capable of interfering to only a very moderate degree, if at all, with the movements of the heart.

W. M., aged forty-five, was a shoemaker; an occa-

sional drinker; he was well until two weeks before his entry into the Boston City Hospital, when, on a damp warm day, he worked all the afternoon with the air from an open window blowing directly upon him. The next day he noticed a slight cold and that his urine was red and less in quantity than normal. When he ate anything he "bloomed right up." He next noticed shortness of breath and pain, sometimes in the right side. A week before his entrance his feet and legs began to swell. On exertion he got sick at his stomach.

He entered the hospital on March 13, when he had a little cough, with no expectoration. The note made on March 14th states that he was a stout man with a dusky complexion, his abdomen and legs somewhat swollen. The heart's dulness extended from above the second intercostal space, outward one and a half inch beyond the nipple on the left side, and along the right border of the sternum. At the apex there was a systolic murmur. The heart's action was rapid, irregular, and not strong, the pulse at the wrist feeble and difficult to count, only an occasional beat being distinctly felt. An attempt to take a sphygmographic tracing at this time was unsuccessful. A diagnosis of mitral valvular disease was made. Pil. cath. comp. no. iv. Tr. digitalis m.x. once in four hours.

March 15th. Free defecation; complexion better, pulse a little stronger, urine of normal color, 1016 acid. Albumen a trace, a few leucocytes and hyaline casts and amorphous urates.

March 16th. Pil. cath. comp. On this day a tracing was taken of which I show a copy.<sup>4</sup>

March 17th. Urine more copious. Free defecation.

March 19th. With stethoscope the heart's rhythm is irregular; four sounds can be heard at the heart, of which the first and third are stronger over nearly the whole heart. At the apex the fourth is inaudible, and part of the time only two sounds are heard.

March 20th. Tracing of carotid very irregular. Omit digitalis.

March 24th. Bloating considerably, some difficulty in breathing. Resume digitalis.

March 30th. Heart beats rapidly at times and at others slowly; radial pulse slow throughout.

April 6th. Vomiting and diarrhoea. Omit digitalis.

April 8th. Died.

I think that few persons in the presence of obvious signs of heart disease, with a small, irregular pulse, enlarged area of cardiac dulness, and a systolic murmur at the apex, would have hesitated to diagnose, as I did, mitral valvular disease; and in fact this affection actually existed in the form of relative insufficiency, probably a secondary development; but it was not all.

Here is what is recorded to have been found:—

Chronic passive congestion of the abdominal organs; emphysema and oedema of the lungs; the right side of the heart was distended very greatly with dark, loose, jelly-like clots, the left side a little hypertrophied. There was no fatty change, the density apparently normal, color and consistence

<sup>4</sup>The tracings of the 16th, 17th, and 19th show increasing strength and regularity of the pulse. That of the 20th shows a loss of tension.

good. No change in the valves; the tricuspid orifice admits three and one-fourth fingers; the mitral, three.

Between the aorta and upper part of the auricle the general surface of the pericardium was thick, dull, and generally echymosed.

I regret very much now that the records are not more minute, and especially that no microscopic examination was made of the ganglia and cords which lay in immediate proximity to the affected part of the pericardium, but I had not at that time (five years ago) seen the suggestive work of M. Peter, and although some dim suggestions of this relationship in locality, and possibly of causation, passed through my mind as accounting more fully than could otherwise be done for the excess of severity in the symptoms, yet they were not sufficient to carry me any further. It seems to me, however, highly probable that we had here to deal with a pericarditis, limited in extent, but of considerable intensity, located at exactly the point where its influence could be most effectually exerted to give rise to neuritis of the great cardiac ganglia and the consequent irregularity and feebleness of the heart, of which the patient died.

I had no intention of trying to collect from the work of M. Peter, or from general literature, an array of cases of affections of the cardiac ganglia with anatomical data, but a very short inquiry convinced me that I might do so without involving myself in any laborious research. M. Peter has much more to say than I have quoted. Under the heads of "Rheumatism of the Heart" and "Angina Pectoris" he gives various cases of his own and quoted from Andral, where the excessive pain or other symptoms were supposed to be due to affection of the ganglia referred to. In fact, one can hardly write or think much of angina pectoris without speculating upon the relations of the cardiac nerves, and it is in a case of the latter kind that M. Peter gives the results of a microscopical examination of the cardiac nerves which were involved in a thickened mass of connective tissue. This was, however, the only one in which actual pathological changes were made out. He cites from M. Bazy a case of aneurism of the aorta with symptoms of angina pectoris, where changes in the cardiac nerves were found, and another from Lancereaux, where the cardiac ganglia were found to be surrounded by a thickened mass of connective tissue with rounded infiltration. I have been successful in finding two other cases, more or less of this kind, both in Parisian hospitals. In the first, a man of fifty-three had violent paroxysms of pain in the breast, down the arm, and in the face. No valvular lesions of the heart were discovered, but the arteries were atheromatous. He died suddenly.

The valves were healthy and there was no obstruction of the coronary arteries. There was a fibrous indurated mass in front of the aorta, in the midst of which the cardiac nerves could not be distinguished. The right pneumogastric was adherent to a large peritracheal lymph gland. Nothing was distinguished in the nerves by the microscope.

In the second a woman, aged sixty-nine, complained of palpitation, dyspnoea, and pains at the

point of the sternum and in the precordial region. These symptoms were liable to be increased in certain circumstances, such as emotional disturbance. The pulse was very frequent while the temperature was normal. There was no abnormal sound at the heart. She died from increasing dyspnoea and gradual weakening of the heart.

Postmortem was found a slight fatty degeneration, dilatation, and atheroma of the aorta. The nervous branches of the cardiac plexus seem to have been stretched by the aortic dilatation, and were found in the midst of a quantity of connective tissue containing a certain number of ganglia (lymph glands?) of various sizes. The left pneumogastric in front of the horizontal portion of the arch of the aorta, where it gives off the recurrent laryngeal, was partly imbedded in a little black mass which seemed a degenerated gland.<sup>6</sup>

The oldest German observation I abridge from Romberg, who quotes from Heine in *Müller's Archiv* in 1811. It was that of a man who said that his heart used to stand still. During these attacks his consciousness was unimpaired, but he had a violent pain extending up the sides of the chest to the back of the neck. No abnormalities in the action of the heart could be discovered in the intervals.

After death it was found that several of the nerves of the cardiac plexus, as well as the phrenic, were dragged upon and compressed by many of the dark-blue cretaceous lymphatic glands in the neighborhood of the bronchi. There were other lesions of the solar plexus and of the nervous centres.

These cases may, I think, be fairly taken to represent the present condition of our knowledge of the pathological anatomy of the cardiac nerves. Bramwell, who may be taken as a representative of the most advanced systematic writers, refers simply to the cases of Peter, and he certainly cannot be justly accused of overlooking the importance of the nervous factor in the symptomatology of cardiac disease.

Possibly further search among cases of aneurism and of angina pectoris might increase our material, but if so it has not yet found its way into the systematic works. In the seven columns of "Heart, nerves of the," in the catalogue of the Surgeon-General's library, I found only a solitary reference to pathology, and that was a recent Paris case without autopsy.

I intended, when I was first asked to present a paper to this meeting, to bring together with much briefer comment this case of my own which I have spoken of, and a number of others which seemed to be in various ways interesting, of fatty degeneration. I find, however, that I have, almost in spite of myself, taken so much time that I shall now do better by presenting some of the chief points given by Peter in the diagnosis of cardiac neuritis than by attempting another subject of so much importance.

After speaking of the examination of the character and localization of the *spontaneous* pain, present in many cases of cardiac disease, as deserving of more care than is sometimes bestowed upon it as a means of diagnosis, beside that which it obviously demands for therapeutic purposes, he describes the

<sup>5</sup> *Progrès Médicale*, 1878.

<sup>6</sup> *Gazette des Hôpitaux*, 1876, page 541.

search throughout the thoracic walls for spots of tenderness as the most important means of diagnosis.

According to him, pain on moderate pressure with the pulp of the finger in the third, fourth, fifth, and sixth left intercostal spaces, passing outward as one passes downward, that is, over the left ventricle, indicates myoecarditis, the maximum of intensity, and sometimes the only manifestation, being in the fifth and sixth spaces. Pain on pressure in the third left intercostal space near the sternum, corresponding to the auriculo-ventricular fissure, means disordered condition of the ganglion of Remak. This, he says, is often found in smokers.

In the second left intercostal space, close to, or upon, the sternum, tenderness indicates neuritis by propagation from aortic lesion.

For the investigation, then, of the cardiac plexus one presses in the third, second, and first intercostal spaces, and then on the sternum close to the second intercostal space, when, if there is neuritis or even neuralgia, it will be manifested by pain.

The second left intercostal space is evidently to be regarded as a sort of centre of painful affections of the cardiac nerves. From this point the pain on pressure may be traced upward in the neck along the line of the pneumogastrics, and finally evoked by pressure upon the second, third, and fourth spinal apophyses, which indicates, according to M. Peter, irritation of the roots of the pneumogastric.

The phrenics may be explored by pressure at their diaphragmatic expansions, along the neck at the attachment of the scalenus anticus to the sternum (*sic*).

For my part, while I cannot help feeling some doubts as to the possibility of a diagnosis so accurate as is claimed by M. Peter, I think that reasons enough have been brought forward to show that the condition of the nervous plexuses of the heart may be capable of profitable investigation during life, and is deserving of more attention than it usually receives from practitioners.

On the anatomical side I might have mentioned, as instances in which the examination of various ganglia seems to be tending toward useful results, the thickening and partial atrophy of the coeliac plexuses, found in some cases of Bright's, and in some of Addison's, disease, and also of the sympathetic ganglia in some cases of exophthalmic goitre. This latter subject, indeed, is closely allied to the one we have been pursuing. Certainly, I think we have in the cardiac plexuses a comparatively untrodden field for the pathological anatomist.

### CHRONIC PROSTATITIS.

BY GEORGE H. TILDEN, M.D., AND E. S. WATSON, M.D.

PROSTATORRHOEA, follicular prostatitis, or chronic prostatitis, as it has been variously called, is but slightly considered by even special authors writing upon genito-urinary surgery. Its importance and far-reaching effects, however, call for a more detailed notice than is usually given to it.

#### ETIOLOGY.

The disease occurs, more frequently than from any other cause, as a residual inflammation, the

result of an acute urethritis. A gonorrhœa which pursues a normal course, anatomically speaking, ends at the membranous urethra, and does not trespass further toward the bladder. It frequently happens, however, that this limit is passed, and then the mucous membrane of the prostatic urethra or the prostate itself is involved in the inflammatory process.

Next to gonorrhœa, masturbation and then venereal excesses furnish the largest quota of cases.

The condition here probably arises from long-continued and oft-repeated hyperæmias induced by such habits. Beside these more common causes, chronic prostatitis sometimes arises as a result of stricture; also from the rough, unskillful introduction of instruments or the presence of a catheter which has been allowed to remain in the bladder, or the administration of irritating drugs, such as cantharides and turpentine. And it is possible that the condition may be excited by the passage of urine containing concretions and sand.

The malady should not be confounded with the hypertrophied prostate, which is a true hypertrophy, taking place only after the fiftieth year, whereas the disease under consideration belongs to youth or middle life, and is essentially inflammatory in its nature.

The affection may be primarily acute and become chronic, or it may be chronic from the beginning, which, as has already been indicated, is determined by its cause.

Anatomically the term prostatitis should be limited to an inflammation which involves the structure of the organ. Clinically it is often impossible to decide whether this is the case, or whether it has its seat upon the mucous membrane of the prostatic urethra only. It probably always originates there, and then may pass on into the follicular structure of the organ afterward.

It is very apt to remain localized about the caput gallinaginis, the ductus prostaticus, and the ejaculatory ducts.

The organ may be enlarged or normal in size or atrophied, the latter when the disease is of long standing; when normal in size it is probable that the mucous membrane alone is affected. The latter is dusky-red or slate-colored, and its capillaries are injected, the surface denuded of epithelium, or occupied by ulcerations. The texture of the organ is less dense and firm than normal. The follicles often contain a dirty or reddish fluid. Occasionally suppuration occurs within the substance of the gland, either because the mouth of a follicular pouch, which is the seat of the inflammatory process, becomes glued together and its contents retained, from which a species of retention cyst arises, or the mucous membrane being broken down urine may find its way into the gland substance and set up suppuration. An abscess so forming ordinarily points in the urethra, but may open into the rectum or into the areolar tissue about the bladder, and lead to serious consequences; the establishment of a fistula into the rectum, exceedingly difficult to heal, being one of them. The collections of pus epithelium and mucus which occupy the follicles of the gland are often washed out and appear in the urine, form-

ing a portion of what are termed mucous shreds, or by the Germans "clap threads" (tripper faden). They may be distinguished from those originating in other parts of the urethra, in that they are shorter, thicker, and more clumpy.

#### SYMPTOMS.

The symptoms of chronic prostatitis may originate in an acute or chronic form. In the first variety the onset is announced to the patient by a sense of weight and throbbing in the perineum, uneasy sensations in the rectum, a greatly increased desire to micturate, and possibly by an attack of retention of urine. If the acute is to give place to a chronic malady, a less conspicuous, but no less characteristic, set of symptoms follows. These, no matter how originating, may be divided into local and general. They are very various, and are not often all present in any one patient. The local symptoms connected with the genito-urinary tract, of which the patient is conscious, are slightly increased frequency of micturition, a sensation of weight, or dull pains in the perineum and about the anus, which are occasional or persistent.

Sometimes slight pain at the end of micturition. There may be undue sensitiveness in the prostatic urethra on the passage of a sound, but as a rule, in long-standing cases at least, the urethras of such patients are anæsthetic.

The sensations are apt to be increased on active exercise.

In cases of short duration, arising from gonorrhœa, there is apt to be frequent sexual desire, and erections; in those of long standing there is a diminution, imperfect erections, and partial or complete impotence from this source. Frequent seminal emissions occur at night, and occasionally one meets with a case of true spermatorrhœa which has its origin in this local inflammation.

The skin of the penis is apt to be more or less anæsthetic.

Frequency of micturition, attended by pain and blood in small quantities at the end of the act, are sometimes so conspicuous as to closely simulate the symptoms of stone in the bladder.

A mucous discharge from the urethra may or may not be noticed by the patient; when it is present the inflammation is probably not wholly confined to the prostate, but exists also anteriorly to it in the urethra; when it is not seen as a separate discharge, it is passed backward into the bladder to mix with the urine.

The explanation given for this phenomenon by Utzmann is that the compressor urethræ is a more powerful muscle than the sphincter vesicæ, and acts as a second and the more important sphincter of the two. When an inflammation has its seat solely behind the compressor urethræ or second sphincter, that is, in the prostatic urethra, the discharge arising from it makes its way in the direction of least resistance; namely, backward through the weaker sphincter vesicæ into the bladder, and not forward through the stronger compressor urethræ, to appear as a urethral discharge. It is not right, therefore, to infer that a patient cannot have chronic prostatitis without the appearance of an urethral discharge.

Another very annoying symptom to the patient is the loss of propelling power to the stream of urine, and the dribbling of a few drops of water after the apparent completion of the act.

The discharge of mucus, when it does occur, takes place more frequently at stool, especially when the patient is of constipated habit, than at other times. Such patients often suffer from the belief that they are affected with spermatorrhœa. Microscopic examination will, however, generally fail to detect spermatozoa. Mucus, epithelial cells, pus, and perhaps a little blood, will be seen to constitute the discharge. Patients sometimes feel a sharp pain in the neck of the bladder or in the anus during coitus, or on defæcation.

An important symptom is inability to urinate for some minutes after feeling the desire and making the attempt to do so.

The general conditions are connected with the nervous symptoms, and are purely subjective. They originate in irritation of the peripheral nerves, with which the prostate is richly supplied. These symptoms as well as the local ones, may almost all arise from pathological changes elsewhere than in the prostate, as well as from it alone; and in their estimation the prostate should not be made their only source. But that they can and do so originate, there is no doubt, in proof of which is the fact that they entirely disappear under treatment directed to the prostate. Among the general symptoms are neuralgic pains, whose favorite situations are the sacro-iliac synchondrosis, the sciatic and the anterior crural regions, and the tip of the coccyx. In one case there existed several distinct areas, in which pressure caused pain; these were beneath each nipple, between the scapulae, and above the crests of the ilia.

These pains vary as to constancy and duration, and may be entirely absent. The patients are often hysterical; there is decided reflex irritability. They are easily alarmed, start at slight noises, or unexpected sights, the nervous system is unstable, they are emotional, and volition is diminished. Changes in disposition are marked, the patients become morose, despondent, anxious, and worried, or apathetic and unable to work or fix the attention. The appearance of the individual varies greatly. As a rule they wear a careworn, anxious, or listless look. But two of the worst cases were in strong, healthy-looking men.

The urine is apt to contain more or less mucus, crystalline deposits of amorphous phosphates and oxalate of lime, more or less prostatic epithelium, sometimes blood and pus, and the "clap threads" already described. Polyuria exists often, and Utzmann declares that very frequently traces of albumen are seen, which disappear if the disease be cured. Spermatozoa are often found.

If the prostate is enlarged or atrophied the change in volume can be felt by rectal examination, though atrophy, unless marked, is difficult to recognize. If suppuration has taken place, the examining finger will sometimes detect losses of substance or cicatricial contractions. With enlargement of the gland a residual urine may be present. This fact is demonstrated by the passage of a catheter immediately after urination. The mucous shreds

and pus are generally seen in the first part of the stream, or, at any rate, are most conspicuous in that portion of it, but, as has already been shown, the discharge may pass into the bladder and thus render the whole urine turbid.

#### TREATMENT.

The treatment is directed to both the local and general conditions, and attention should be paid to both. As local measures, counter-irritation to the perineum, with cantharidal collodion or tincture of iodine, being careful not to let the fluid run on to the scrotum or anus, is beneficial. There is no need to blister the surface severely; one side of the *raphé* can be painted over at a time, and after a few days the other, and this should be kept up for several days, during which the patient need not be confined, but allowed to pursue his usual occupations. In connection with this, prostatic injections of nitrate of silver, applied by means of an *Utzmann's* syringe catheter, fenestrated on the sides, and connected with a small syringe containing a drachm of the solution, is perhaps the most useful remedy. Most authors recommend a solution of from ten to twenty grains to the ounce. This produces vesical tenesmus, often slight hemorrhage, and great temporary discomfort, which, though they pass off in the course of a few hours, are, during their presence, very unpleasant. We do not think they are followed by any better results than when a solution of from two grains to five grains to one ounce is used. Anything over five grains is likely to produce the symptoms above mentioned; anything below, avoids them. One can begin with a two-grain solution and increase to five grains. The application should be made once or twice a week, for a period of from four to eight weeks, when all benefit which is likely to accrue from them at any one time will have taken place. The advantage of this form of administering the drug is that it is applied to the prostatic urethra and not elsewhere. To insure this, the index finger of the left hand may be inserted into the rectum, and the prostatic urethra localized by it; the tip of the catheter should then be passed upon it as a guide to the neck of the bladder, and the fluid injected.

As an adjunct to this treatment, the passage of large sounds once a week, cutting the meatus, if necessary, to allow of their introduction, or the application of a hollow, double-current catheter, through which a current of cold water can be made to flow, retained in position for from five to six minutes, is valuable.

Resorcin, and various antiseptic and astringent solutions, may be applied to the prostatic urethra, or drugs may be locally administered in the form of soluble bougies, amongst which those of iodoform, deposited by a *probe constrictive*, have been the most useful in our hands, but the most decided effects will be produced by the nitrate of silver solution.

The local treatment above described is especially valuable in cases of long standing, in which the emotional condition is well marked, where neuralgias, defective erections, frequent seminal emissions, and a prostate atrophied, or at any rate not enlarged or tender, are the prominent symptoms. When the gland is enlarged and tender, and approaches a con-

dition of subacute inflammation, instrumental interference may only increase the trouble and be followed by chills and urethral fever.

Cases in which there is loss of sexual power are benefited by electricity, one pole being applied over the spine and the other to the perineum, or, when obstinate, one electrode may be inserted into the rectum or prostatic urethra.

Among the more important elements in the general treatment is the restoration of the patient's *morale*, the power to accomplish which depends of course largely upon the personal qualities of the physician. If he can succeed in reestablishing the volition to the point of inducing the patient to carry out the treatment resolutely much will have been accomplished.

Daily out-door exercise should be insisted upon; walking is, perhaps, the best form in which it can be taken. Horseback riding is condemned by most authors as tending to produce congestion of the parts, and bicycling is open to the same objection. Cold baths, best taken in the morning, are beneficial, especially in the long-standing cases. Where the condition is more subacute, hot sitzbaths and irrigation of the rectum with hot water will be found to give much comfort. When the course of local treatment is ended a change to mountain air and an out-door life should be urged. A constipated habit is apt to exist, which tends to increase the congestion of the parts, and this is well counteracted by the administration of *strychnia* in small doses for a considerable period, which at the same time supplies a tonic.

Two or three drugs are useful as adjuvants in the treatment. Gouley recommends the two following:—

Quinine sulph.	℥ii.
Acid arsenic.	gr. i.
Strychnia sulph.	gr. i.
Acid phos. dil.	ʒi.
Syr. ferri sulphos.	ʒiv.
5℥. ter in die.	
Tr. ferri chlor.	} . . . . . āā gttss. v.
Tr. cantharid.	
Vini ergot.	

Both of these we have found useful.

Abstinence from fermented or malt liquors is important; claret may, perhaps, be taken. Drinking or eating before going to bed should be avoided.

It is desirable to sleep in a cool room and on a hard mattress.

Moderate sexual indulgence is of advantage, and matrimony is advised by some physicians with a view to securing this. This opens an ethical question which each must decide for himself. Besides the chance of the patient's being actually impotent the disposition of a sexual hypochondriac is pretty sure to bring unhappiness to his partner, and so unless we are sure that the patient is cured or on the fair road to cure, we advise strongly against matrimony in such cases. If an enlargement of the organ exists, iodide of potash, twenty grains, combined with acetate of potash, twenty grains, is recommended by *Utzmann*.

Surgeons are very apt to regard this class of cases as *blees noies*, and often partake of the sense of discouragement which the patient himself feels

about the case. It must be frankly confessed that there are a certain number of cases which, with the most conscientious treatment, one fails to cure; where the melancholia is so deep-seated that even if in one's own judgment the local conditions are greatly bettered the patient remains convinced that his state is as bad as ever. For such we know of nothing that is likely to benefit them, but believe that they form a minority. A few cases follow to illustrate the various points which have been spoken of:

**CASE I. Chronic Prostatitis; Neuralgias and Despondency the Prominent Symptoms; No Improvement on Treatment.**—H. G., aged twenty-seven. Gonorrhoea three years ago, which ran a usual course. No further urethral trouble until nine months ago, when, without exciting cause, so far as the patient will state, a thin urethral discharge reappeared. This was intermittent, but was noticeable independent of erections or of defecation. About six months after he had first observed it he began to suffer from neuralgic pains in the perineum, tip of coccyx, and anterior erural regions; felt decided lassitude and muscular weakness, and became very despondent. The change in disposition was noticeable to himself and to his associates.

The patient is a small, slight, pale man, wearing an apathetic look. Expressed entire hopelessness as to his present condition, and had but slight hopes of his recovery.

The urine contains a slight trace of albumen, a little mucus and pus, prostatic epithelium, a few mucous shreds, and is otherwise normal. The normal size of the urethra is 31 (French); the meatus admits a sound of this size, which passes readily into the bladder. A little pus was seen on the sound upon its removal. The prostatic urethra is exceedingly sensitive.

Rectal examination shows the prostate to be slightly enlarged.

An examination of the other organs of the body shows nothing abnormal in connection with them.

The treatment, for one month, consisted in the daily administration of tr. meis vomice, counter-irritation to the perineum with tinct. iodini from time to time, and for two weeks irrigation of the rectum with hot water for ten minutes at a time, daily. Temporary improvement followed, and then a relapse to the original condition.

The cold sound, the passage of large steel sounds, and the insertion of prostatic soluble bougies of zinc and iodoform, were then given a thorough trial with a similar result. The mucous shreds and pus, however, greatly diminished during this treatment, and the trace of albumen disappeared.

A month passed in the mountains after this greatly improved his condition, but the benefit was only short-lived, and all his old symptoms reappeared after a few weeks of city life. Shortly after this the patient was lost sight of.

**CASE II. Chronic Prostatitis, the result of Stricture and Neglected Gonorrhoea. Prominent Symptoms: Frequent and Painful Micturition, Melancholia, Neuralgias; Cure.**—F. M., aged forty. Gleet and symptoms of stricture for nine years. Internal urethrotomy performed a year ago; he neglected the after-treatment and a slight gleet persisted. A 33 (French) sound passed readily into the bladder,

showing that there was no tendency to recontraction of the strictured portion of the urethra.

But the patient had gleet, muscular weakness, neuralgias about perineum, great despondency, suicidal thoughts, and entire hopelessness in regard to his condition.

The urine contained mucous shreds from the prostate, prostatic epithelium, pus, and mucus.

The patient had increased frequency of, and pain on, micturition. The prostate was seen to be enlarged on rectal examination. The other organs of the body were normal. Strychnia and dilute phosphoric acid were administered internally.

Prostatic injections of one drachm of a solution of nitrate of silver, three grains to one ounce, were given twice weekly, and the perineum was mildly blistered. In eight weeks the patient professed himself as entirely well, and all the symptoms had disappeared except an occasional mucous shred in the urine.

**CASE III. Chronic Prostatitis complicated by Cystitis, a Fistula from the Prostate into the Rectum; Residual Urine; Prominent Symptoms: Frequent and Painful Micturition, Malaise; Instrumental Interference harmful.**—M., aged thirty-one. Gonorrhoea seven years ago; gleet ever since; four years ago a second gonorrhoea, followed by acute suppurative prostatitis; abscess opening into the rectum; establishment of a fistula. The prostate has remained enlarged ever since; residual urine has been also present.

Rectal examination shows a very large hard, but not tender, prostate. There is a slight urethral discharge. The urine is one of chronic cystitis.

The urethra was explored on two separate days, and admitted a No. 28 (French) sound; the second examination was followed by urethral fever lasting a week, and no further treatment was undertaken.

**CASE IV. Chronic Prostatitis, originating in Masturbation; Prominent Symptom: Frequent and Painful Micturition. Improvement.**—S., aged twenty-eight. No history or evidence of gonorrhoea. The patient has masturbated for a long time. He seeks relief on account of very frequent and painful micturition, a symptom which, beginning some months since, has gradually increased in severity, until now the calls to urinate are as often as every fifteen minutes, and very painful. He has imperfect erections and no sexual desire.

The urine contains mucous shreds; is otherwise normal. The penis is small, the urethra very sensitive, especially in the prostatic portion. The vasa deferentia are somewhat enlarged and hardened, but the prostate is normal in size and not sensitive.

The treatment, which was followed for more than a year, consisted in the administration of tonics, such as iron, quinine, strychnia, and cod-liver oil. The use of the cold sound and the passage of large steel sounds at regular intervals at first; later, local application to prostatic urethra of soluble bougies of iodoform, acetate of lead, and sulphate of zinc, with belladonna. The meatus was incised.

Each new form of treatment was followed by improvement, succeeded by relapse until toward the last months of the time, when the frequent and painful micturition gradually disappeared, and the patient's general condition improved.

QUALITY OF SOME OF THE PHARMACOPŒAL DRUGS IN COMMON USE.<sup>1</sup>

BY B. E. DAVENPORT, M.D.

UPOON the proper quality of the drugs of which we as physicians make use in the treatment of our cases depends very largely the results of our medications. If they are not of exactly the quality that they should be, all of our skill exercised in their selection may be of no avail. Deficiency or excess of action may each prove equally disastrous. Directly from the former in cases of sudden emergency, it is self-evident that it may happen, as with ergot in a case of post-partum hemorrhage. Indirectly it may also as truly be the cause. A patient having become accustomed to take a very largely increased dose of an inferior preparation in order to get the desired results, may subsequently upon a refilling of the recipe get the preparation of the full and proper strength. Now, upon taking the accustomed quantity as a dose an unexpected amount of action is experienced; it may be even with fatal results. Many of us who have had charge of dispensary districts have seen probable fatal results in cases of infants from the variability in the strength of a much too well known and popularly used "soothing syrup." It was to secure uniformity in the composition of medicinal preparations which was largely the original cause of the formation of the various pharmacopœias, and it is to ensure this uniformity that the Pharmacopœia is enforced by law in most civilized countries. That some such support is needed in this country, and even in this most enlightened State of Massachusetts, has been amply shown by the results of the examination made by the State Board of Health, Lunacy, and Charity into the quality of the drugs sold in this State during the year 1882-83, which they have lately published.

According to that report, out of 680 samples of drugs examined, which were mostly the more important articles of the Pharmacopœia, considered as medicines, 284, or a little over forty-one per cent. of them, were found not to be fairly of the quality required by the statute. Some of the most flagrant cases were among the most important drugs, as, for instance, in laudanum, where some samples were only one sixth as strong in morphine as others. The average strength in 100 samples was only eighty per cent. of what it ought to have been. There were eighty-two per cent. of the samples which fell below the required minimum strength. Yet no tincture of the whole Pharmacopœia is probably more generally carefully prepared than this one. As the ingredients are costly it is deemed desirable to get as much out of it as possible, so as to leave little to be thrown away with the drugs. One thrifty tradesman of our city, of whom I am told, thought even these drugs too valuable to be thus wasted, as the opium itself had cost him so much; he therefore dried them, and used them to make Dover's powders from. As for the camphorated tincture of opium there appears to be even a much greater range of variability than in the simple tincture or laudanum. Very fortunate is it,

considering the ascertained variability in the preparations of opium, that our morphine salts have been so uniformly found to be of full pharmacopœial quality. The powdered opium itself was also usually good.

In cinchona barks the crude drug is not nearly of so uniformly reliable a character as is the opium, for not more than half the samples examined were found to be up to the standard of quality required of them. The galenical preparations from the bark, as in the case of the bark itself, are of quite an uncertain alkaloidal strength, while the simple salts of the alkaloids were in almost all cases of good quality, just as was the case with the morphine salts. In those cases which were not up to the standard it was the more expensive salt, such as quinine, which had an excessive impurity of some one of the other and cheaper cinchona alkaloids. In these salts absolute chemical purity from the other three principal alkaloids is not demanded, but a limit of not over one per cent. of the other alkaloids is allowed.

A very shrewd form of adulteration of quinine has lately been discovered in New York City in quite a number of instances. It is the addition of milk sugar to the salt. Its presence would not be detected by the more usual tests which would be used upon a sample of quinine, such, for instance, as with concentrated sulphuric acid for the color caused by most other organic substances, or by the Kerner test, which depends upon the varying solubilities of the four alkaloids in water and ammonia. As the quinine is the least soluble in water, but the most in the ammonia, this detects the presence of more than one per cent. of quinidine or cinchonidine, or of more than mere traces of cinchonine. The presence of the sugar is most easily demonstrated by boiling up the quinine sample with three times its weight of the ninety-one per cent. alcohol of the Pharmacopœia. In this the quinine itself is easily soluble, while the sugar would remain nearly wholly undissolved. This residue, when fully washed out with further alcohol, would be found to be sweet, and to respond to all the tests for milk sugar.

In the compound salts of quinine, such as those with iron, there has been found the great variation of those containing from only a quarter part of the full amount to those containing even a little more than the full amount of quinine. Only fifteen per cent. of the samples, however, contained the at present required twelve per cent. of quinine, while formerly it was sixteen per cent. Furthermore, there has been the almost universal substitution of the unauthorized green scale salt containing ammonia, the so-called soluble salt, and which usually claims but ten per cent. of quinine, for the brown pharmacopœial salt, which does not contain ammonia, but is, as it is intended to be, a scale which goes very slowly into solution, although it is in time fully soluble. This is a preparation intended for use in pills, etc., where its slow solubility is desirable. Those whose wish is for a more quickly soluble preparation should make use of the liquor ferri and quinine citratæ which has been prepared to meet their special needs.

Another drug, jalap, which has been in extensive use by our physicians, has been found, upon exam-

<sup>1</sup> Read before the Boston Society for Medical Observation, March 2, 1885.

ination, to be commonly very inferior to the requirements of the Pharmacopœia. By this it is required to have not less than twelve per cent. of resin, of which not more than ten per cent. should be soluble in ether. Not more than one sample in six has been found to come up to these requirements, and most of the wholesale druggists of this city have told me that they were unable to furnish at present that which did. This, in their minds, seemed to show that the standard of the Pharmacopœia was too high, while to me it only showed the prevalence of the inferior article. Selected samples will yield twenty-two per cent. of the resin, while the good commercial samples should yield from twelve to eighteen per cent. That the majority of any drug offered in the market does not equal the standard required of it may prove either of two facts: first, that the standard may have been set too high, or, secondly, that the majority of the article offered is adulterated, or of a quality inferior to what it should be, and that consequently there is a very great need of an enforced standard. Just this was the case in our city a few years ago, when ninety per cent. of the samples of milk analyzed were found to be inferior to the legal standard, and therefore the producers then generally thought that the standard was a little too high. But now, since they have been shown that milk, when taken straight as their own cows gave it, was very generally above the standard, they have been convinced that the standard is all right, but that it is the adulteration which is the prevalent error which ought to be complained of.

The bromide and iodide of potassium are two much used chemicals which in the great majority of cases are not of the quality called for in the Pharmacopœia. The unfortunate trade custom prevails which requires that they should be in opaque porcelain white crystals. To secure this appearance they have to contain a considerable impurity of alkaline carbonate which unfits them for use in many mixtures into which many physicians seem to have a desire to combine them. Presence of an excessive amount of chlorides, sulphates, and even water, are the rule rather than the exception. The price has been ranging so very close upon the cost of manufacture that the having even only one per cent. of water present may make the difference between loss or profit in the sales. It is the pure, dry, colorless, translucent crystals that physicians should learn to demand to have dispensed for them.

The compound spirit of ether, or Hoffmann's anodyne, is an important drug, of which probably many physicians never have seen a true sample, the imitation being so very much the more common of the two, most manufacturing chemists using therefore a residuum by-product left in the process of rectifying crude ether. The chief excuse offered for this fraud is the great cost of the true ethereal oil, which is about fifty times that of the same weight of alcohol, and this plus the other costs of the manufacture. As alcohol is at present worth about forty cents per pound the ethereal oil is therefore worth not less than \$20 per pound, while the pharmacopœial preparation, as ours is mixed with an equal volume of stronger ether, should cost about \$10 per pound. The common commercial compound spirit of ether has averaged at the price

of about fifty cents per pound, while it should have been nearly four times that sum. The cheap preparation, however, does not usually contain as much as one fourth part of the proper amount of the expensive ingredient, ethereal oil, but commonly it has none of it at all. The above-mentioned by-product from the rectification being variously modified by the addition of alcohol, ether, fixed oils, etc., so as to make it match in taste, smell, opalescence, and the other physical properties, a standard sample of the true preparation kept by the manufacturer. A drug prepared as an imitation in this manner must be most uncertain in its action, and it cannot surprise any one that the product as obtained from different stores varies very much in its properties, and very often must disappoint the reasonable expectations of physicians. It is for this reason, I suppose, that this important preparation has so much fallen into disuse in these latter days.

## Reports of Societies.

### PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

C. M. GREEN, M.D., SECRETARY.

ANNUAL MEETING, April 25, 1885. The President, DR. JAMES C. WHITE, in the chair.

DR. ROBERT T. EDES read a paper on

#### SOME NON-VALVULAR DISEASES OF THE HEART.<sup>1</sup>

DR. MINOT thought there was nothing improbable in the idea of the so-called functional derangements of the heart being dependent upon structural changes in the nerves or ganglia, which were not necessarily permanent. The researches of Charcot and Vulpian have shown that paralysis following diphtheria probably depends upon structural alteration of the cord or nerves, or both. This alteration, however, must be transient in the large number of cases which recover.

DR. F. C. SHATTUCK expressed his obligation to Dr. Edes for bringing this interesting and important subject before the Society. Hitherto our efforts have been directed to perfecting our knowledge of the valves and heart muscles with the result that we are now in a position to diagnose many of the pathological changes in these structures with great accuracy. Faulty innervation of the so-called "functional" character has been dwelt upon more or less by all writers on cardiac disease, and frequently comes under the notice of every practising physician. The reader has well shown how little attention structural changes in the cardiac ganglia has received in the past from either pathologists or clinicians, and how very limited is our real knowledge in regard to them. The subject is a difficult one, much more difficult than the study of the lesions of the muscular and fibrous portions of the heart; but that fact makes it none the less important that our attention should be called to it.

In several cases of pericarditis without appreciable serous effusion coming on insidiously during the stage of absorption of left pleurisy, and apparently secondary to that disease, the speaker had

<sup>1</sup> See page 463.

been struck by great irregularity in the action of the heart. In the absence of pain, as well as of any other evidence of *acute* inflammation, and of effusion, the symptom was striking and the speaker had been at a loss to account for it fully; perhaps the cause lay in some such condition of things as Dr. Edes describes; but the changes in the cardiac ganglia, if changes there were, were less serious, as the patient ultimately recovered perfectly.

#### THE PERIOD OF INCUBATION OF TYPHOID FEVER.

Dr. F. C. SHATTUCK reported the following facts which suggest the possibility that the poison of typhoid fever may lie dormant in the system at least four weeks before the disease begins to manifest itself. He had recently had under his care a young lady with mild but unmistakable typhoid, who on January 10th moved into a new house from one which she and her family had occupied for some years, but left because there were bad smells which the landlord refused to try to remedy. February 6th she was taken down with the fever, and at the request of Dr. S. the Board of Health examined both houses. The new house was in perfect order; but the soil-pipe of the old house was broken at a point so near the cold-air box of the furnace that the odor of peppermint came up the registers. The family drank only spring water, so the disease cannot be laid to Pegan Brook and the inhabitants of Natick. Careful inquiry failed to show any other cause for the attack.

Dr. MINOT asked if the period of incubation of typhoid fever could be five or six weeks.

Dr. SHATTUCK said that he did not mean to assert that his patient contracted her disease in the house from which she moved: the facts were reported only for what they were worth. In one house there was a satisfactory cause, in the other there was not. Our knowledge is not complete as to the duration of the stage of incubation of the infectious diseases, and one reason which led to the reporting of the case was the positive assertion of one of the physicians connected with the Board of Health that so long a period of incubation of typhoid fever is impossible. Our knowledge does not warrant such a positive statement one way or the other.

Dr. MINOT alluded to the great difficulty of detecting the source of infectious disease in many cases. In a family occupying a recently built house in which no pains or expense were spared to make the drainage and plumbing as perfect as possible, several cases of diphtheria occurred. The most minute investigation having failed to show any sanitary defect, the house was thoroughly fumigated with burning sulphur; but on the return of the family, several days afterward, a fresh case occurred, which proved fatal.

#### INCIDENTAL BUSINESS.

The Treasurer submitted his annual report, showing the income of the Society to have been \$563.93, and the expenditures \$494.72; there remained in the treasury \$69.21.

The Treasurer announced that the ordinary income of the Society would not be sufficient to meet the expenses of the ensuing year; on the Treasurer's

suggestion it was therefore voted that an extra assessment of one dollar be levied on each member, to be collected at the annual meeting of the Massachusetts Medical Society.

The Committee on Social Meetings reported an expenditure of \$50, and a balance on hand of \$58.73. It was voted that the Committee continue to provide supper at the stated meetings of the Society.

It was also voted that the President be authorized to appoint at his discretion delegates to attend the annual meetings of the American Medical Association without calling a special meeting of the Society for the purpose of so doing.

The Nominating Committee submitted its report, and the Society proceeded to ballot for officers for the ensuing year. It was subsequently declared by the tellers and announced by the President that the nominees of the Committee had been duly elected.

Officers of the Suffolk District Medical Society, elected April 25, 1885:—

President, George B. Shattuck. Vice-President, John Homans. Secretary, Charles M. Green. Treasurer, Edward M. Buckingham. Librarian, B. Joy Jeffries. Commissioner of Trials, Charles W. Swan. District Nominating Committee, Richard M. Hodges. Committee of Supervision: Benjamin S. Shaw, Samuel A. Green. Committee on Social Meetings: Calvin Stevens, Francis H. Brown, George W. Gay, Abner Post. Censors: A. N. Blodgett, E. G. Cutler, T. M. Rotch, F. C. Shattuck, F. H. Williams. Councilors: S. L. Abbot, James Ayer, H. H. A. Beach, H. J. Bigelow, C. J. Blake, J. G. Blake, H. I. Bowditch, A. T. Cabot, D. W. Cheever, Hall Curtis, H. Derby, O. W. Doe, F. W. Draper, J. R. Draper, S. H. Durgin, Thomas Dwight, R. T. Edes, R. H. Fitz, C. F. Folsom, G. W. Gay, J. O. Green, S. A. Green, F. B. Greenough, W. H. H. Hastings, R. M. Hodges, C. D. Homans, John Homans, W. Ingalls, B. J. Jeffries, F. I. Knight, S. W. Langmaid, M. B. Leonard, G. H. Lyman, F. Minot, C. B. Porter, John P. Reynolds, W. L. Richardson, G. C. Shattuck, B. S. Shaw, A. D. Sinclair, D. H. Storer, A. M. Sumner, C. W. Swan, G. G. Tarbell, O. F. Wadsworth, J. C. Warren, Thomas Waterman, James C. White, W. G. Wheeler, E. N. Whittier, H. W. Williams.

#### BOSTON SOCIETY FOR MEDICAL OBSERVATION.

CHARLES H. WILLIAMS, M.D., SECRETARY.

MARCH 2, 1885.

Dr. F. H. WATSON read a paper on

#### CHRONIC PROSTATITIS,

which is printed on pp. 496-499.

Dr. POIRER said the most sensitive part of the urethra was in the prostatic portion, or just in front of it. In these cases he had found a cold steel sound of the greatest service. It dilates the urethra to its normal size; it seems to press the blood out of the velvety and inflamed surface of the mucous membrane and reduces the sensitiveness of the parts.

He considered tonics internally and cold steel locally of the greatest benefit; also the use of soluble bougies is a very valuable means of treatment in many cases. The hot-water douche is often of great benefit, and in cystitis irrigating the rectum often relieves the bladder; the water may be from 115° to 120°. He mentioned one case where there was a hyperæsthetic condition of the urethra, in which coitus produced almost immediate ejaculation, followed by an intense priapism, often lasting from six to eight hours; the patient was relieved by the use of the steel sound. He also spoke of the mental condition which was often present, and could generally be traced to the reading of some quack advertisement, and called attention to the need of combating this condition, which may often entirely unfit the patient for work, although his other symptoms may not be serious.

Dr. A. T. CAROT said that those cases of chronic prostatic inflammation that he had seen might be divided roughly into two classes: First, cases dependent upon excessive or perverted sexual excitement; secondly, cases in which the prostatic urethra was the seat of an inflammation that had extended to it from some neighboring part (urethritis or cystitis). In patients of the first class adjustment of the sexual hygiene, tonics, and counter-irritation over the perineum, with the occasional passage of a large sound, usually sufficed to bring about a cure. In cases of the second class, which were characterized by the presence of pus in the first part of the urine passed, the deep injections of nitrate of silver in the manner described by Dr. Watson were found most efficacious. The benefit derived from these injections seemed to be increased by the passage of a sound immediately before their use. He would be inclined to include some of the enlarged prostates seen in old men among the chronic inflammatory processes. These cases are intermittent in their symptoms, a period of quietude being followed by a stage of inflammation, during which there is a marked increase in the size of the gland and in the difficulty of micturition. The prostate during these attacks is hot and tender, and leeching the perineum often does much to control the symptoms. Each of these accessions of inflammation, as it subsides, leaves the gland with a slight augmentation of size.

Dr. TILDEX said that all these symptoms might be found in other conditions than inflammation of the prostate; he had seen such a case where the trouble was caused by an anterior stricture, and one was only justified in treating the prostate locally when other troubles had been eliminated. Enlargement of the prostate should always be determined by rectal examination. He thought the injections of nitrate of silver were very serviceable; he had often used general tonics and a pill of ergot, strychnia, and cannabis indica.

Dr. WATSON said when we get no discharge from the anterior urethra, but find prostatic epithelium and shreds of mucus, with swelling of the prostate gland, we may be sure of prostatic trouble. He had never seen a case of prostatitis caused by bicycling or horseback riding, but where the trouble already existed these exercises would increase it.

Dr. B. F. DAVENPORT then read a paper on

#### THE QUALITY OF THE PHARMACOPŒIAL DRUGS IN COMMON USE.<sup>1</sup>

Dr. EDES spoke of the increasing use of alkaloids in the place of the crude drugs. He considered it a great gain, as the dose was more easily regulated and the quality of the drug was much better, as the alkaloids were much less likely to be adulterated. He mentioned the extract of cannabis indica as especially untrustworthy, whereas the tannate of cannabis was much more reliable, and in using opium, belladonna, or cinchona, the alkaloids were much more used than formerly.

Dr. DEBLOIS showed a plaster nasal splint. Two bandages are incorporated into the plaster, which is fitted to the nose while soft; on hardening, the plaster holds the parts comfortably in place, and it can be kept in place by the two bands, one tied behind the ears and head, the other over the top of the head.

#### THE NEW YORK ACADEMY OF MEDICINE.

STATED meeting, May 7, 1885.

##### THE PHYSICAL EXAMINATION OF WEAK CHESTS AND DIFFERENTIAL DIAGNOSIS OF THE SEVERAL FORMS OF EARLY PHTHISIS.

Dr. E. DARWIN HUDSON, JR., read the paper of the evening on this subject. The interpretation of physical signs, he said, could never be dissociated from some theory of the nature of the existing disease. For nearly fifty years the specific nature of all phthisis and its transmission solely by heredity, according to the pathology of Bayle and Louis, remained unquestioned; but the last twenty years had witnessed almost a revolution of opinion as to the prominence, or causative relation, of miliary tubercle in phthisis, and a majority of all investigators and of the profession had come to acknowledge the three forms of phthisis, the catarrhal, fibroid, and tubercular, as so clearly presented by Sir Andrew Clark and Professor Loomis. There was also reason to believe that in very many cases the disease exists in a mixed form, and he felt satisfied that in consideration of the different methods of origin and the complex nature of a large proportion of cases, our physical exploration was incomplete if we discovered only the presence of cavities and softening, or the evidences of local consolidation. A complete diagnosis should include, *in extenso*, an exact knowledge of the condition of each portion of the respiratory apparatus, including the air-passages, vesicles, interstitial tissue, and pleura; and the views which he wished to present related to the methods of examination most useful in studying weak chests with tendencies to phthisis, in detecting the times of transition from danger to disease, and in differentiating the early forms of phthisis.

Later on he spoke of the importance of examining all parts of the chest, and called special attention to two areas, often affording most valuable information, which were almost wholly passed over by most examiners. These were the high axillary region and the interscapular spaces. In the first, the initial area of pneumonic consolidation in cases of irregular pleuropneumonia and in certain low and

<sup>1</sup> See page 500

indefinite forms of pneumonia, as evidenced by bronchial breathing, had alone been found. In the interseapular region are the larger bronchial trunks and the hilus of each lung, close to the posterior wall of the thorax; but in order that the area could be examined with advantage, it was necessary that the patient should cross his arms in front, each upward at an angle of 45°, with the hand on either side grasping the convexity of the shoulder, and should also bend the head well forward. In this way the interseapular space could be more than doubled in area, while the muscles were rendered tense and thin.

*Inspection.* He was convinced that in a large proportion of chest cases, and in a large number of phthisical ones, an approximate diagnosis could be made by inspection alone. It was highly desirable, therefore, to extend it, in detail, to all the structures of the thoracic wall. Among other points, he spoke of the significance of the direction of the clavicle; stating that when it was deflected upward and backward, at an angle of thirty, thirty-five, or forty-five degrees, the chest development had evidently been most defective during a long term of years, and the presumption was in favor of the existence of lungs, undeveloped at their apices, which had more fully occupied the supraclavicular and clavicular areas. He also dwelt upon the relation which slight lateral curvatures of the spine have to the condition of the respiratory organs (claiming that in many cases their appearance was subsequent to the occurrence of pronounced attacks of pleuritis or pleuropneumonia, or a period of long-continued unilateral thoracic pain with associated cough), and on the importance of closely observing and interpreting, with their full significance, the changes in the individual intercostal spaces, and also in the supraclavicular space, suprasternal notch, and epigastrium. Dr. Hudson explained in the following way the fact that the apices are preferably attacked in phthisis: (1) The apices are so frequently enfeebled by contraction of the upper part of the bony thorax, — whether by want of muscular activity and development, or by rounded shoulders through carelessness and indolence, or through confining work at desk or trade. (2) The apex region in this enfeebled condition is soonest reached and most easily invaded by the frequently occurring catarrhal inflammations. (3) Because the apices, when invaded by hyperæmia or catarrhal processes, are not favorably affected by the energetic force of cough.

*Mensuration and Palpation.* He had but a word to say in regard to the former, but mentioned, in regard to palpation as a method of chest examination, that it was particularly valuable as relates to the subject of fremitus. Fremitus was especially instructive for negative diagnosis; often indicating the normal chest by a characteristic vibration communicated to the hands, which could not be misinterpreted.

*Percussion.* The exclusively pulmonary origin of percussion sounds was easily disproved; the elasticity of the chest-wall being undoubtedly an essential factor or contributor to the percussion note. In contracted chests and in the mixed forms

of early phthisis percussion leads to no positive diagnosis, until supplemented by auscultation.

*Myoïdema.* Dr. Hudson devoted considerable time to this phenomenon, which was first reported by Graves and Stokes, in 1850. The result of his personal observations was: (1) That it frequently exists in established phthisis, where the long-standing and progressive intrathoracic disease has wasted the body. (2) That it frequently exists in incipient phthisis. (3) That it is exceptionally present in any other disease, and its presence in any such case justifies a suspicion of phthisis. In but one case, a convalescent typhoid, did it seem pronounced, and so exceptional was this case that, though chest disease was not demonstrable, he felt that its early manifestations might soon appear. He usually percussed with a quick blow upon the costal cartilages of either side; when instantly two or three little conoidal tumefactions appeared. He had sometimes seen in the intercostal space an associated reflex muscle wave, which floated away toward the shoulder until lost. He believed the so-called “myoidema” to be a true cutaneous reflex, and said he had come to regard it as of much diagnostic value. In concluding this subject he passed around a photograph representing two of these tumefactions on the chest-walls.

*Auscultation.* The absence or modification of the vesicular murmur had always, and properly, been regarded as a first warning of phthisis; but the presence or absence, fullness of development or enfeeblement of the vesicular murmur was not of so great value in differentiating the three forms of phthisis, and especially the relative proportion of each in mixed phthisis. He had for a long time come to regard the study and application of the conducted whisper as of equal or greater value than the study of changed vesicular murmur and conducted voice, and of far wider application in determining and differentiating the early steps of the three definite forms and the many mixed cases of phthisis. By employing the smaller tube of the stethoscope in connection with the incisive, high-pitched whisper, close comparison of adjacent limited areas, as contiguous lobules, could be made to great advantage. He also especially valued the whisper tests in distinguishing a healthy lung from one but slightly diseased. The occurrence of a hæmoptysis was often the occasion of a first examination of a hitherto unsuspected or a long-neglected chest; and the physical signs were widely different, as a rule, during the first hours, or days, succeeding a hæmoptysis.

In all disease the effort of the physician, Dr. Hudson said in conclusion, should be specially directed to arriving at an early and accurate diagnosis; and with reference to pulmonary phthisis it may be truly said that the usefulness of the medical attendant is greatest in the cure and restoration of the enfeebled chest and chests invaded to a comparatively slight extent by disease. The fully developed consumption is so difficult to combat that it is an *opprobrium medicinæ* that so little can be done.

#### DISCUSSION.

DR. ALFRED L. LOOMIS said he was much pleased that the author of the paper had so sharply defined

the physical signs met with in early phthisis, and while he could not agree with him in every particular, in the main he was entirely willing to endorse the positions taken. In regard to inspection, he had come more and more to realize the importance of the method. It often happened that the appearance of the chest alone was sufficient for the diagnosis of early phthisis. Although in 1,200 or 1,500 chests he had found only 10 per cent. that were perfectly symmetrical naturally, the general inspection of the chest afforded certain knowledge to the skilled examiner which could not be derived from any other source. There were certain areas which were of special importance. When he first began the study of thoracic diseases, and for many years afterward, he was accustomed to look principally to the infraclavicular spaces, as he had been taught; but for a considerable time past now he had come to regard the signs found in the scapular spaces of much greater importance. Many and many a time he had found the signs of early phthisis there when they could not be detected anywhere else. In a large number of cases the disease commenced in this region, and he regarded this area of particular value from the fact that here he often found evidences of disease on both sides, while elsewhere it was impossible to ascertain that it existed except on one side. It was the localized bronchitis which told us of the phthisical trouble. The axillary space was also of great importance, and when there was extensive consolidation of the central portion of the lung, he had yet to meet the first instance in which the physical signs in this area did not indicate the condition.

In regard to percussion, he said he would be inclined to lay more stress on the value of the method than Dr. Hudson apparently did. As often practised, with sledgehammer-like blows, always in one direction, he thought that very little information could be gained from it; but a single tap, light though firm, would often give a more exact idea of the amount of infiltration present in any case than could be obtained by auscultation. Percussion was of special importance in the scapular space, where a peculiar dull note (a simple loss of resonance) was of peculiar significance. In the auscultation of the voice, the whisper was of far more value than the spoken tone; particularly in giving information in regard to the condition of the pleura. There were certain changes which gave rise to very few physical signs which could be accurately determined by means of the whispered voice. In regard to the respiratory murmur, he recognized three changes of importance in early phthisis, namely, as regards softness, harshness, and interruption. If the murmur was feeble, as well as harsh, it indicated an affection of the pleura, probably tubercular in character. By the peculiar harshness of the vesicular murmur he had detected the commencement of acute phthisis months before the easily recognized signs of the condition had appeared.

Dr. PACK spoke in confirmation of Dr. Hudson's views in regard to myoidema.

Dr. E. G. JANEWAY said in reference to myoidema that he had studied the matter sufficiently to convince himself of the unreliability of the phenomenon as a diagnostic sign. He had seen it fre-

quently in other diseases than phthisis, and in various muscles all over the body. He believed that it could often be found in emaciated subjects, whatever the cause of the loss of flesh, and thought that the only reason why it had not been so generally observed in other wasting diseases besides phthisis was because in them the physician was not ordinarily apt to tap the chest. As he had just said, myoidema was not limited to the chest; and, as a rule, he had found it much more perfectly developed over the biceps and deltoid muscles than over the pectoralis major. He believed that the phenomenon was undoubtedly purely muscular. In the early stages of phthisis the most that we could make out by physical signs was condensation, thickening, consolidation, and local bronchitis. While all the signs had their value (palpation probably the least of any), there are always chances of error, and the true significance of the condition present might not be imparted by them. He would attach considerable importance to signs of irritation of the bronchi, and râles in the small bronchi, limited to the supra and infraclavicular spaces, he thought was of great significance. When there were evidences of consolidation, it would not do to trust to a single examination, since pneumonias not infrequently occurred at the apex of the lung. Such pneumonias ran a characteristic course, and were apt to involve the posterior and middle parts of the upper lobe, leaving the anterior portion untouched. At the present time he should not be willing to make a positive diagnosis without resorting to a careful microscopic examination of the sputa. The character and number of bacilli present in any given case were of great importance in determining the kind of phthisis from which the patient was suffering. Dr. Janeway laid stress upon the necessity of making the microscopic examinations with great care and deliberation, and in accordance with the most approved methods, and said that in more than one instance an incorrect diagnosis had been made through lack of proper caution. In conclusion, he spoke of the importance of inquiring into the past history of the patient in every case, since the signs of early phthisis might apparently be present, when in reality these are simply evidences of a hyaline disease which had existed in the lungs years before.

Dr. HENSON remarked that in the limits of such a paper he could not hope to cover the entire ground, and that there were many other points which he would gladly have touched upon had time permitted. He had endeavored to indicate, however, in as plain a manner as possible the physical characteristics, not so much of typical cases of phthisis as of those of a more obscure variety. In regard to myoidema he said that he wished it to be distinctly understood that the phenomenon in question was *not* a muscle wave, but a true cutaneous reflex. In the paper he had been particular to say that he had sometimes seen an associated reflex muscle wave in the intercostal space, which floated away toward the shoulder until lost. He thought Dr. Janeway would hardly dispute the fact that there was a real elevation of the skin in urticaria and cutis asneria, and since this was the case, he believed it was reasonable to suppose that the so-called myoidema was a cutaneous phenomenon. Finlayson and Gairdner

expressly stated that the designation given by Lawson Tait, myoedema, was a misnomer. For some time past Dr. Booth had examined every patient coming under his observation in the department for nervous diseases, of the Manhattan Eye and Ear Hospital, for true myoedema, and had not found it in a single instance; and, as he had mentioned in the paper, he had himself observed it in no cases where phthisis was not present, with the exception of one or two of convalescence from typhoid fever. That it was not a muscular phenomenon he thought was proved by the fact that the tumefactions were caused by striking upon the costal cartilages, where there was no muscular tissue.

DR. JANEWAY said he would like to add but a single word to what he had said before. He had carefully examined the photograph exhibited by Dr. Hudson to make sure that the phenomenon treated of in the paper was the same thing which he himself understood by the term myoedema, and he found that it was, precisely. He thought Dr. Hudson could hardly successfully deny that the fibres of the pectoralis major extended over the costal cartilages.

#### PATHOLOGICAL SOCIETY OF PHILADELPHIA.

THURSDAY evening, April 23, 1885. The President, DR. E. O. SHAKESPEARE, in the chair.

##### NOTES ON THE MORBID ANATOMY OF PNEUMONIA.

DR. OSLER read a paper summarizing his experience while pathologist at the Montreal General Hospital. Of 105 autopsies in cases of lobar pneumonia, of which notes were available, five were discarded for various reasons. The mortality at the hospital is high on account of the large percentage of grave cases which are admitted, very many in persons debilitated and dissipated.

Of the one hundred cases seventy were males and thirty females. Of ninety-four instances in which the age was given, there were eleven cases under twenty years; twelve between twentieth and thirtieth; eighteen between the thirtieth and fortieth; twenty-one between the fortieth and fiftieth; twelve between the fiftieth and sixtieth years, and twenty cases over sixty. In fifty-one cases the right lung was affected; in thirty-two the left, in seventeen both. Other details were given of the various lobes affected. The heaviest lung weighed was 2,303 grammes, and in eight instances the affected organ weighed over 2,000 grammes. In about fifty per cent. of the cases there was red hepatization; in thirty per cent. mixed red and gray, and in about twenty per cent. gray hepatization. The condition of the pleural air-passages, bronchial glands, and unaffected portions of the lung tissue were described. Among the terminations there were four instances of abscess formation, three cases of gangrene, and one in which there was a process of fibroid induration beginning in the lung. This case was a man aged fifty-five, admitted with pneumonia of the right lung five days after the initial chill. Resolution did not occur and he died in the fifth week.

*Postmortem.* The right lung was found solid,

grayish in color, and in many areas the tissue had a smooth, homogeneous, translucent aspect, and in these a fibroid change was going on; the alveolar walls were thickened and the fibrous plugs in the air-cells seemed undergoing transformation into connective tissue (a slide was shown illustrating this). There were no caseous portions and no tubercles.

As to the other organs, the frequency with which large firm clots were found in the heart was specially dwelt upon. In only thirty-five instances was the spleen much enlarged. In one it weighed 670 grammes. In twenty-five per cent. there were marked fibroid changes in the kidneys. Of the complication, there were five cases of pericarditis and sixteen cases of endocarditis. In eight instances the meninges of the brain were inflamed, in five of them associated with ulcerative endocarditis. In five instances there was acute croupous or membranous colitis, and in one instance croupous gastritis.

DR. TRYON, in the discussion of Professor Osler's paper, said that he had been rather incredulous of the termination of croupous pneumonia in fibroid induration, but the specimen exhibited by Dr. Osler demonstrates conclusively that such a condition exists. The facts presented in the paper are such as are not generally collated.

Collective reports of autopsies in cases of particular forms of disease would be of great value in the study of pathology. Dr. Formad asked Dr. Osler why his was not a case of acute phthisis. Croupous pneumonia is a very common accident in acute phthisis.

It is croupous pneumonia which causes deaths, which is well shown by recent investigations of Mercier, of the University of Pennsylvania.

DR. FORMAD did not believe that croupous pneumonia can last five weeks.

DR. SHAKESPEARE said that the remarks of Dr. Osler about the frequent existence of very firm clots in the right heart, extending into the ventricles, can be corroborated by any one who makes autopsies of cases of pneumonia at hospitals. He had seen them in cases of phthisis quite as extensive and firm, reaching into the vessel going to the afflicted part of the lung. It is interesting to note the systemic involvement of these cases of croupous pneumonia, and the affection of internal organs, as well as lungs, in the process which has been regarded as a local disease. We have to do with a general wide-reaching affection, rather than local inflammation. The opinion was advanced by Dr. Osler that the exudate in the air-cells organized, that the process in the organization of the croupous exudate is similar to that in the clot in arteries after ligation, and that comparison was the point which Dr. Shakespeare wanted to bring out. Dr. Shakespeare said that he did not believe that a blood clot in a vessel ever organizes, and his opinion is based on facts detailed in an investigation which he has published on the healing of arteries after ligation. The vessel healed, not by the agency of the white cells caught in the meshes of the reticulum, but by proliferation of the endothelium of the tunica intima and subjacent connective-tissue cells. He thought there was reason to believe that there is in

this process in the lungs an analogue of the process after ligation.

We have to do with an outgrowth of the inter-alveolar walls. The ground which Dr. Shakespear takes is purely that of analogy to the process in a blood clot in a ligatured artery.

DR. OSLER, in closing the discussion, said that it was well known that croupous pneumonia might persist five or six weeks, or even longer, before resolution took place.

It was difficult for any one who had not had the experience to realize the anxiety which such a case would cause. He had reported two such cases of delayed resolution, one in the fourth week and one in the eighth, both with perfect recovery. He was quite aware of the difficulty in distinguishing certain cases of acute phthisis from pneumonia, and had seen a case with Dr. Ross in which the diagnosis was for some time in doubt, but in the case in question the person had been under observation from the outset, and the symptoms were those of ordinary pneumonia.

Postmortem there were no caseous masses, no milary tubercles, only the condition already described. The termination in fibroid induration, though rare, was perfectly well recognized. In Cornil and Ranvier's Manual, as well as in Green's Pathology, was a figure which might have been taken from the slide under the microscope.

DR. M. H. FUSSELL, of Manayunk, presented specimens from a case of

#### PRIMARY TUBERCULOSIS OF THE KIDNEYS.

The reporter never saw the subject alive from whom the specimens were removed, having performed the post-mortem examination for a friend.

Case of Edward B., aged forty; single; by trade a paper-maker. In following his calling he was forced to stand in a dust-loaded atmosphere from morning until night. He worked at this trade from boyhood, steadily, with the exception of four years during the late war. His grandfather died of bladder trouble; his father died of apoplexy; his mother, brothers, and sisters are all living and healthy. He was always a robust man; his weight was one hundred and seventy pounds, and he never had any serious illness; he had gonorrhoea during the war. Four years ago while in camp he made a misstep and fell. The next morning he passed much blood in his urine; previously to this he was perfectly well. From this time until death he was troubled with slight pain in his loins and with frequent micturition; his urine was sometimes bloody, sometimes milky. The patient's bladder finally became incontinent and he was forced to wear a urinal.

The patient's general strength did not seem to suffer until the past six months, when he began to lose flesh and strength, and at death he was much emaciated. He had never had any cough or diarrhoea. Two weeks before death he began to vomit; this increased in frequency until he was unable to retain anything on his stomach. Just before death, breathing was rapid and full. The patient was very restless, vomited, and passed urine freely. The pupils were dilated.

DR. FUSSELL examined the urine several times.

The specific gravity ranged from 1.002 to 1.010. Large amounts were passed. Albumen was present. The microscope showed pus, blood, and granular epithelium. Many of the cells were irregular in shape, the pyramidal form predominating. No casts were found at any time. Unfortunately, a critical physical examination of the patient was never made. At different times surgeons had sounded him for stone and had failed to find any.

*Postmortem.* Nothing especial noted on the exterior of the body.

*Thorax.* Heart about normal in size. The muscle looks normal, and contains a large amount of fluid blood and currant-jelly clots. A small decolorized clot on the left side. Valves normal.

*Lungs.* Both pleural cavities obliterated. The pleuritic adhesions were tough, the lungs being with difficulty torn from the cavity. In places the pleura was much thickened. The surface of both lungs was studded with milary tubercles. On section the lung substance was crepitant and studded with myriads of milary tubercles. No caseous masses nor cavities were found in either lung. The bronchial glands were enlarged, not caseous.

*Abdomen.* Viscera in normal position, peritoneum free from tubercles and of a healthy look.

Liver of normal size and color. Over the surface a few stellate cicatrices were noted, but no tubercles seen on the surface nor on section of the organ. The bile-ducts free.

The stomach contained greenish-black fluid, the mucous membrane of a greenish color corresponding to the contained fluid. The rugae were much enlarged, especially at the cardiac end. Near the pylorus there was a small injected spot.

*Kidneys.* The right measures six inches in length and three in width, and is of a reddish hue; the surface is studded with tubercles; on stripping off the capsule the larger of these remain with the kidney structure, while some of the smaller ones are torn off. On section, the cortical substance is seen to have a thickness of about one third of an inch. Numerous foci of softening are seen. Three are of the size of a nickel five-cent piece. There are very many smaller ones, situated mostly in the pyramids. Numerous milary tubercles throughout the substance of the kidney. The foci of softening are evidently due to breaking down of the tubercles. The ureter is dilated, measuring half an inch across in some portions. The mucous membrane is ulcerated. The pelvis of the kidney is not dilated and shows milary tubercles.

The left kidney is large, and is converted into five or six cysts. There is but little kidney substance remaining. The surface of the kidney is studded with a few tubercles. The cysts are lined by a thick, leathery membrane which can be stripped from the kidney substance. On puncturing the cysts, a perfectly clear serous fluid at first escaped, soon followed by a milky substance containing some cheesy masses. The pelvis is smaller than normal, the ureter entirely occluded.

The suprarenal capsule had undergone degeneration and is of a uniform yellowish-white color, and presented tubercles.

The bladder was slightly contracted, the mucous membrane indicated, the muscular coat being

exposed. The vesical trigone was of vivid red color and studded with milary tubercles.

The intestines were normal, no enlargement of lymphatic elements. The mesenteric glands were slightly enlarged. The prostate gland and spleen were not examined.

PROF. WM. OSLER kindly made sections of the kidney and suprarenal capsule, and the reporter is indebted to him for the following report:—

First, Extensive, wide-spread, small-celled infiltration between tubules and Malpighian tufts.

Second, Distinct milary tubercles with centrally placed giant cells.

Third, Areas of softening and disintegration. Tubercle bacilli carefully sought for but only two undoubted specimens found.

Suprarenal capsule showed milary tubercle with centrally placed giant cells.

DR. FORMAD referred to a similar specimen which had been exhibited by Professor Tyson at a former meeting of the Society.

DR. OSLER remarked that Dr. Fussell's case corresponded in all essentials to what we know as tubercular nephritis. The bacilli, however, were scarce and difficult to find. Since the report of Dr. Tyson's case a few weeks ago, he had had occasion to look over the notes of several cases and found that they formed a complete series from cases of unilateral disease to instances with tuberculosis of the entire urinary tract and general infection. The condition was not infrequently met with accidentally in persons dead of other affections.

*Tubercle bacilli in the urine.* Dr. Osler showed a slide of pus from the urine in another case of tubercular kidney with the tubercle bacilli stained.

The President, DR. SHAKEPEARE, reported a case of

#### INTESTINAL STRICTURE.

The patient was admitted to the Philadelphia Hospital one week previous to her death, under the care of Dr. Evans, the house physician. She had obstinate constipation, followed by stercoraceous vomiting. She suffered acutely, lapsed into an unconscious state, and died, all treatment proving ineffectual.

At the autopsy the thoracic organs were found apparently normal. In the right iliac fossa a lobulated tumor was apparent on opening the abdominal cavity. The colon was distended with gas in the transverse portion, and in the descending portion was narrow. The ascending and transverse portions had hardened faces. There was a double twist of the intestine and two strictures; one in the ilium two inches above the ileocecal valve, and one two inches below the valve. They would not admit the finger. There was a ring of hardened tissue in each stricture. There was congestion of the mucous membrane in the small intestine and adhesion of the first part of the descending colon on its under surface to the abdominal parietes. The kidneys were normal; a large tumor of the right ovary was also present, attached to the uterine.

DR. FORMAD, who made the autopsy, remarked that acute peritonitis had, in this case, become chronic and that it was the contraction which made the strictures. The cause was probably the abdominal tumor. He was not aware that there was a

case on record where a tumor produced stricture. The constriction was due to outside pressure.

### Recent Literature.

*Injuries of the Spine and Spinal Cord without apparent Mechanical Lesion, and Nervous Shock, in their Surgical and Medico-legal Aspects.* By HERBERT W. PAGE. Second edition. Philadelphia: P. Blakiston, Son & Co. 1885. Pp. xii.—397.

It is only two years since the first edition of the excellent work appeared. But few changes have been made. We can recommend the new edition as heartily as the first; it is by far the best book which has yet been written upon the subject.

*Neuralgia and the Diseases that Resemble It.* By FRANCIS E. ANSTIE. New York and London: G. P. Putnam's Sons. 1885.

This is a timely reprint of Dr. Anstie's work which appeared in 1871. It will be gratifying to those who desire to obtain this classical treatise to know that the Putnams have reprinted it. It is a pity that the index has been omitted in the reprint.

Those who have not had an opportunity to read Anstie's work will find it worth their while to procure and read it now. While saying this, we do not mean to accept the whole of what is stated. We should make objections more especially to the author's views of the pathology of the disease.

*Lectures on Diseases of the Nervous System, Especially in Women.* By S. WEIR MITCHELL. Second edition. Philadelphia: Lea Brothers & Co. 1884.

The first edition of this book appeared in 1881. Some of the lectures have been altered and three new ones added. It is scarcely necessary to repeat our commendation of the work as given in the notice of the first edition. The three new chapters are interesting and instructive, though they are chiefly devoted to reports of very rare cases, such as few physicians will meet.

One chapter is upon hysterical joints. The history of a young girl is given, who suffered from pain in the knee with swelling, rigidity of the leg, and periodically local rise in temperature. The symptoms were so similar to inflammation that her physician, acting upon the advice of European surgeons, laid open the joint, in hopes that ankylosis would result, and so a cure be obtained. The articular surfaces were normal, the enlargement was due to plastic infiltration of the fatty and connective tissues outside the capsule. Ankylosis did not result.

The chapters on "Hysteria and organic disease of the spine," "The rectum and defecation in hysteria," are equally interesting, and the cases given are full of instruction.

In the closing paragraph of the book, Dr. Mitchell has italicized a sentence in the second edition which was not thus emphasized in the previous edition. Speaking of the rest treatment, he says: "It is a plan never, in my opinion, to be used where exercise, outdoor life, tonics, or change have not been thoroughly tested."

# Medical and Surgical Journal.

THURSDAY, MAY 24, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by CUPPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM AND COMPANY,

283 WASHINGTON STREET, BOSTON, MASS.

## AN EPIDEMIC OF TYPHOID FEVER FROM CONTAMINATED SEWAGE.

DRS. M. S. FRENCH and E. O. SHAKESPEARE, having been requested by the Mayor of Philadelphia to visit Plymouth, near Wilkesbarre, Pennsylvania, where an epidemic has existed for the last month, read a preliminary report before the Philadelphia County Medical Society, May 13th, and will present a full report before their State Medical Society at its meeting in Scranton on the twenty-seventh instant.

They found that Plymouth was situated in a valley, on the border of the river Susquehanna. The city of Wilkesbarre, of 30,000 inhabitants, delivers its sewage into the river only two miles above, and the refuse-water from abattoirs and the coal mines is also pumped into the river. The neighborhood of Plymouth is supplied by water from three sources: the Susquehanna River, shallow wells, and by a reservoir fed by mountain streams, the latter usually being sufficient to supply the needs of the town; but on account of the springs being frozen the water company, about March 20th, commenced pumping the river-water into its mains, but discontinued a week later.

Upon investigating the subject, it was found that during February and March a case of typhoid fever had been under treatment on the mountain near the water-course which supplied the reservoir, and the nurse had thrown the excreta out on the frozen ground on the border of the stream. In March, a thaw with rain came, and washed the excretions into the reservoir, and the solution was subsequently distributed through the pipes to a large part of the city. In ten days' time the epidemic began, fifty cases of typhoid fever occurring daily between the fifth and fifteenth of April. The part of the town supplied exclusively by well-water and the river-water escaped entirely, with the exception of a few inhabitants who were in the habit of drinking some of the mountain-water in the morning at home, before going to their daily work. In other parts of the town the extent of the disease was in direct ratio to the amount of spring-water which was used. Not-

withstanding the filthy character of the water from the river it did not originate any cases of the disease.

The investigation of this instructive epidemic, in which some twelve hundred cases of typhoid fever occurred in a small town with a mortality of nearly one hundred, emphasizes some important points and principles: (1) That the epidemic was caused by an infected water-supply; (2) that a single case of typhoid fever may originate an epidemic if the excreta are allowed to pollute drinking-water; (3) that the water-supply may be contaminated by sewage, and yet in the absence of the specific poison not cause typhoid fever; (4) that a freezing temperature does not destroy the activity of the typhoid-fever germ, nor does dilution. Prior to the visit of Drs. French and Shakespeare, the sickness had been attributed to the use of the river-water, and the water company was enjoined and forbidden to use the water from the Susquehanna River, under penalty of having its charter revoked.

## PRIMITIVE DRY PLEURISY AND FIBROID LUNG.

THE relations of the above conditions were chosen by the distinguished Sir Andrew Clark as the subject of the Lunnian lectures for the current year. The well-deserved eminence of the lecturer and the great interest of the subject with which he deals render it a pleasure as well as a duty to notice his utterances, in the hope that some of our readers may refer to recent British journals and read the lectures in full. Here it is only possible for us to attempt a brief presentation of some of the most salient features of the subject.

Although there are those whose opinion is entitled to great respect who deny either the existence of such a thing as primitive dry pleurisy or its causal relation to fibroid disease of the lung, we have no hesitation in ranging ourselves alongside of Sir Andrew in affirming that the former occurs, and that the latter sometimes springs directly from it. In the first lecture, twelve cases, selected apparently from a much larger number in the experience of the author, are reported; while some of these are certainly not conclusive, most of them are so; and the great length of time during which some of them were followed up greatly enhances their interest.

It is not, of course, meant that primary dry pleurisy is the only cause of the fibroid lung; it may ensue on pleurisy with effusion, pneumonia, or bronchitis; it may also either follow a true phthisis as well as eventuate in tubercular disease.

Primitive dry pleurisy may terminate in recovery after a longer or shorter time; it may continue with fresh outbreaks and new formation of false membranes without extending into the lung itself; it may spread along the interlobular septa and the

bloodvessels, more and more destroying the vesicular structure of the lung tissue. In the latter event some of the bronchi, vessels, and lymphatics are obstructed and obliterated, while others may be dilated. Ectasis of the blood and lymph-passages does not form so striking a feature, either pathologically or clinically, as does ectasis of the bronchi, by which cavities of large size may be formed, especially if ulceration attack the walls and invade the neighboring tissue. Bronchiectatic cavities are of comparatively little consequence as long as their contents can be freely discharged; if, however, the secretion be retained sufficiently long to undergo decomposition the case wears a grave aspect. Secretion may, of course, be hopelessly pent up and result either in abscess, or, the fluid portions being absorbed, in a caseous mass. The same forces which dilate the canals of the lung produce emphysema here and there; the supervention of tuberculosis in a fibroid lung has been already alluded to. This is briefly the chain of changes which may follow directly on a primitive dry pleurisy with the lapse of time.

If the pleurisy has not invaded the lung, the patient is apt to have the appearance of health, and may either experience no subjective indications of disease, or only a slight and inconstant cough with scanty expectoration, and some local discomfort in the affected side; sometimes he is himself conscious of the pleural friction. If, on the hand, the lung has been attacked the chief clinical feature is the association of marked and long-standing anatomical changes in that organ, almost always unilateral, with a good or fair condition of the general nutrition and strength. The patient may be fat, and his only real complaint be of inability to exert himself without shortness of breath, though more or less cough and expectoration are nearly constant.

The typical bronchiectatic patient is thin, stooping, and cyanotic with severe cough and profuse expectoration, purulent or even fetid in character, and yet displays a combination of mental and physical energy not to be met with in any other disease." Another peculiarity of bronchiectasis is that it is often bilateral. In fibroid lung with or without bronchial dilatation the heart is often drawn out of place by the contraction of the side; and the increased resistance in the pulmonary circuit throws extra work upon the right ventricle, failure of which is manifested by the well-known signs of venous stasis, cyanosis, dropsy, and passive congestion of the internal organs giving rise to albuminuria and dyspeptic symptoms. Even when all these are present with proper management the patient may often be restored to a surprising degree of activity. Thus we see what a marked contrast these cases present to those of ordinary phthisis, and yet many a mistake in diagnosis has been made with them, patients living much longer and more active lives than was expected by their medical advisers.

The physical signs of these conditions, although different from those of tubercular disease, do not differ as much as do the rational signs, the careful study of which is reviving from the neglect they suffered for a long time after the introduction and perfection of methods of physical exploration.

Sir Andrew seems to admit the great importance of the presence of the bacillus tuberculosis in the sputum and thinks that a bronchiectatic can be distinguished with certainty from a tubercular cavity only by this criterion. It strikes us that his fears are not well grounded as to the active dissent likely to be excited by the assertion that chronic ulcerative and destructive processes may go on in the lungs without the presence of these organisms—in other words, that there is a phthisis which is not tubercular. The question is one of terminology rather than of fact. The pathology of these lectures is very old-fashioned in some respects; and in some points, not exclusively pathological, there is a certain lack of clearness at which we are surprised. As to this, however, we trust that our readers who have not already done so will put themselves in a position to form their own opinions.

#### TENICIDE THERAPEUTICS.

BERANGER-FERAUD has published an interesting *résumé* of all cases of tenia occurring at the marine hospitals of Saint Mandrier and Cherbourg for a period of twenty-three years (1860 to 1882 inclusive). At both hospitals it was always the unarmed tenia—the tenia mediocanellata—which was observed; the tenia solium, so common in this country that it is, according to Flint, almost the only kind met with, was not seen in one unequivocal instance. At Saint Mandrier there were 593 admissions for tapeworm during the time mentioned; at Cherbourg, 418. It appears from each year's statistics that tenia cases have been steadily on the increase since 1860, the figure at Cherbourg being 1 for 1861 against 39 for 1882, and Saint Mandrier giving a similarly augmented proportion. As for the symptomatology of the cases reported by Beranger-Feraud, the patients were all adults, well and strong, and no special morbid phenomena were noted; certainly nothing on which alone a diagnosis could have been based. Out of 118 cases carefully watched by the *interne*, there was not one in which there were any very pronounced nervous disturbances. In both hospitals dyspepsia with augmentation, diminution, or perversion of the appetite, diarrhoea, colicky pains, a creeping sensation in the intestines, etc., was complained of by many of the patients, but the greater number were, for the first time, apprized of the existence of the parasite by the presence of the joints (proglottides) in the stools.

In the treatment of these patients a variety of

tæniifuge agents was used, the results of which are minutely given. In two cases only was turpentine administered; in one the larger part of the worm without the head was expelled, in the other several joints only were passed. The author recalls previous experiences of his own with this medicament during the campaign of Crimea. In eight trials with turpentine, only one was successful in bringing away the entire worm; in the seven other cases large portions of the parasite came away, but no more than might readily follow the administration of any energetic purgative. Moreover, the ingestion of a large dose of turpentine is always exceedingly disagreeable, and less than one or two ounces is of no avail. It is hardly necessary to add that such a dose may provoke a troublesome irritation of the alimentary canal, long manifesting itself by gastric disturbance and by diarrhoea. On the whole, Beranger-Feraud advises that henceforth turpentine be expunged from the list of tæniifuge medicines, as being both disagreeable and dangerous, and almost sure to disappoint. As for Filix Mas, the trials made in the two military hospitals were not encouraging, and in no instance did expulsion of the head of the entozoön follow its administration. It is possible that a poor preparation of the oil may have been used, or it may not have been given *secundum artem*, for if we may trust the testimony of Dr. Gull, in Guy's Hospital Reports (3d series, vol. i.), this anthelmintic was formerly singularly successful in English practice.

Graziadei,<sup>1</sup> in view of the unpleasant results sometimes accompanying the administration of this drug, used thymol in a number of cases, forty-five in all. The parasite was in all the cases the ankylostoma, and the success, according to this author, was perfect in every instance. The method of administration was as follows: First, a purgative was given, then after its operation, six doses, each of two grammes of thymol, were given in cachets every two hours, followed in each case by two teaspoonfuls of some generous wine. Usually a sensation of warmth in the stomach, ensued, with tinnitus, sweating, and sometimes a feeling of heat in the urethra on micturition. There were signs of slight intoxication with loquacity followed by deep sleep. Three to twelve hours after the last dose of the medicine diarrhoea usually sets in which brings away more or less of the ankylostoma. If the microscope shows none of the eggs of the parasite, the cure is considered complete and tonics only are given. But if the ova are discovered in the stools, at the end of five days the process is repeated and may be gone through even four or five times.

Pumpkin seeds were employed in thirty cases at Cherbourg, with a percentage of five per cent. in which the entire worm was expelled after the use of this medicine. The tæniifuge was generally given hulled and in the form of a paste with milk, the

patient having been kept on a milk diet the day before. From three to four ounces of the mashed seeds is a suitable dose to take at one time. In some instances this dose was preceded by an ounce of castor oil the evening before, and followed by a second draught of the oil two hours after the ingestion of the anthelmintic.

Koosso was employed at Cherbourg 203 times, with complete success in 22 cases, expulsion of the worm without the head in 126, and entire want of success in 39; 16 cases were not afterward heard from. At Saint Mandrier there were, in 173 cases, 14 complete expulsions and 159 failures. In other words, the Abyssinian anthelmintic was successful in 12 per cent. at Cherbourg, and in 6 per cent. at Saint Mandrier.

Pomegranate bark (*Punica granatum*) gave the best results of all the anthelmintics at the hospitals Saint Mandrier and Cherbourg. Out of 131 trials, it brought away the whole worm in 57, that is, in 43 per cent. There was, besides, a radical cure in several cases where the head was not found, but where there was never afterward the appearance of any segments in the dejections.

The pomegranate is given in the form of the bark of the root, a decoction being prepared by boiling two ounces in two pints of water down to a pint, of which quantity one third is given every hour till the whole is taken. It is desirable that the decoction should be made of the fresh bark and taken fasting.

It is unquestionable that the recent discovery by Tanret in the pomegranate bark of the alkaloids, to which he has given the name *pellétérines*, has been a step in the way of progress in the treatment of an affection often so trying to both patient and physician, and brilliant results from the use of these mixed alkaloids have been reported by Laboulbène, Dujardin-Beaumetz, and Delrochemare. The trials which Beranger-Feraud has made with these *pellétérines* have resulted in a radical cure in 76 per cent. of cases, that is, out of 41 essays there was complete expulsion of the tænia in 37.

As this new remedy has, of late, been introduced into this country (where we already hear good reports from its use), it seems desirable to reproduce the minute directions which Beranger-Feraud has given for its administration. The *pellétérine* is furnished to the trade only in bottles, each containing one dose.

#### MEDICAL NOTES.

—One of the latest wiles of the Adversary (meaning, of course, the peripatetic "agent") is to ask for a word with the doctor and to say that he was requested to make an appointment for Mr. So and So, of Worcester or Fitchburg, who will arrive in town next Tuesday at half-past eleven. The physician replies that he cannot without inconven-

<sup>1</sup> *Revue des Sciences Médicales*, April, 1885.

ience be in at that hour, but mentions his office-hours, and in a glow of grateful feeling at his extending practice, complies with the visitor's request for his card. Visitor then remarks casually that the reason he was given the message was because of his having business with a neighboring doctor whom he has always supplied with safety-matches. A sample package is then naturally produced, and—the victory is won. The defences have been carried, and nothing awaits the bewildered garrison but rapine and slaughter. A similar artifice wrought the destruction of Ilium. *Tineo Demos et dona ferentes.*

—At the forthcoming meeting of the British Medical Association, in the section of surgery, it is arranged that the following two subjects of great practical interest shall be discussed: (1) Mr. Treves (London) will introduce the subject of "Operative Interference in Intestinal Obstruction." (2) Mr. Reginald Harrison (Liverpool) will read a paper introductory to a debate on "Bladder Tumors, their Diagnosis and Treatment."

—The *Indian Medical Gazette* has recently changed ownership, and the excellent reputation it already bears seems likely to suffer nothing from the new hands into which it passes. This journal is almost the only specimen of its kind from the "low latitudes," and the diseases peculiar to the tropics have always received abundant illustration and comment in its columns, while from its exchanges it culls for the Orient the best medical progress of the Occident.

#### PHILADELPHIA.

—The University of Pennsylvania closed the one hundredth and twentieth annual session of its Medical Department, and held its one hundred and eleventh annual commencement on May 1st, graduating one hundred and eight candidates for the degree of M.D. At the same time the degree of D.D.S. was conferred upon forty-nine graduates of the Dental Department. The Trustees have decided not to fill the vacancy in the Faculty caused by the resignation of Dr. Harrison Allen for the present, and have appointed Dr. Edward T. Reichert to lecture on physiology during the coming year.

—At the Jefferson College it has been announced that Professor Pancoast has tendered his resignation, to take effect at the close of the next session. It is not expected, however, that any vacancy will be caused by this resignation, as it is probable that another member of the Faculty will be transferred to this chair.

—At the last meeting of the Medical Jurisprudence Society, May 12th, on motion of R. C. McMartin, Esq., a report was presented of a special committee on "The Legislation Necessary in Relation to Habitual Drunkards, Opium-eaters, and Similar

Classes." The report brought out the facts that there is no power anywhere lodged to interfere with the person or property of an inebriate until the disgrace of an inquest has been incurred, and that there is no legal provision enabling friends of the patient to use the only class of houses fitted for the cure of their cases.

Legislation on the following points was urged: Permission to use public or licensed insane asylums for the custody of habitual inebriates. Authorizing the detention of such persons for a necessary time. Permitting friends to procure the appointment of a committee on persons under twenty-five years of age without an inquest. Defining the power of the committee to restrain the person.

Regulating the removal of restraint, so that a fair opportunity may be given to test the fact of reformation or cure, and authorize an immediate restoration of the restraint on property and person. Such legislation must be accompanied with restrictions or guards against the abuse of these powers by securing the property of the patient from any use other than such as he could be compelled to apply it to by law, if he were of sound mind. All temptation to profit by the commitment of an inebriate must be removed. The test of the necessity of committing the patient must be determined by jury trial.

—Dr. B. F. Baer, President of the Philadelphia Obstetrical Society, has resigned from the University of Pennsylvania, where he was engaged in the Out-Patient Department, and has entered the Polyclinic as Professor of Gynecology. Dr. H. Augustus Wilson has returned from Europe, after two years' absence, and is now Professor of Fractures and Dislocations in the Polyclinic.

—Dr. A. P. Brubaker has been elected to the Chair of Physiology in the Pennsylvania Dental College, to succeed Professor Chapman.

### Correspondence.

#### DEATH FROM OVERDOSE OF OPIUM.

NEWPORT, R. I., April 16, 1885.

*Mr. Editor*,—I send you the following case of opium-poisoning, which you may deem worthy of putting on record.

W. A. C., aged sixteen; stout boy; had been treated for three days for a cough with small doses of nauseant sedatives. On the night of the third day, he received, by order of his physician, ten grains of Dover's powder, and one-sixth grain of morphine *per os*. He was found dead in bed the next morning. He had taken altogether in the three days about two and three-fourths grains of opium and one-sixth grain of morphine.

When called to see him the next morning I found his skin livid and pupils dilated.

The moral is double: Care in administering opium where the respiration is embarrassed, and care in dealing with the present high grade of the drug.

Very truly yours,

F. J. B. CONNOR, Assistant Surgeon U. S. N.

## Miscellany.

### LONGEVITY OF STATESMEN AND PUBLIC OFFICIALS.

THE most recent of the "Toner Lectures," a course given at irregular intervals under the endowment of Dr. J. M. Toner, of Washington, is one by Dr. Charles A. Mills on "Mental overwork and premature disease among public and professional men." The lecture, like its predecessors, most of which have been given by well-known physicians, has been published by the Smithsonian Institute in pamphlet form. The cases, sixty in number, collected by the author, are divided into two classes: men in public and official life, and professional men; the former class included twenty-eight members, distributed as follows: Cabinet officer, one; senators, eight; representatives in Congress, ten; department officials, five; governors, two; candidates for important offices, two.

The average longevity of men in the higher walks of political life in this country is regarded as considerably below the average of those who occupy similar positions in England. Comparing, so far as information was available, the ages at death of United States congressmen and members of the English Parliament, who have died since 1860, the following results were obtained: Fifty-nine United States senators gave an average of sixty-one years; one hundred and forty-six United States representatives an average of fifty-five years; the average for both being, therefore, fifty-eight years. One hundred and twenty-one members of Parliament gave the remarkable average age at death of sixty-eight years.

Taking twenty-five of those that might be regarded as the most eminent American statesman of the last one hundred years, and comparing their ages at death with those of the same number of the most distinguished English statesmen, the United States gave an average of sixty-nine years, and Great Britain of seventy, practically the same. It may be added, in this connection, that Mr. Gladstone is in the seventy-sixth year of his age, Lord John Russell, who was an active member of the House of Lords to the time of his death, after a long career in the House of Commons, was ninety years old when he died, and Lord Palmerston, who died while occupying the position of premier, was eighty-one years old. Lord Beaconsfield, Earl Derby, Lord Aberdeen, Lord Melbourne, and Earl Grey were also old men when holding places of power, and did some of their best work at an age when most American public men have ceased to do anything important.

### THE POSTERIOR SPLINT FOR THE FOREARM.

Is a very practical article in *The Polytechnic* (February 15th) by Dr. Charles W. DuRoi, called "Suggestions from dispensary experience for the surgery of general practice," the author has a word to say about splints, in which he emphasizes the importance of the element of weight in that connection. The lighter the better, he considers a good principle. In fractures of the forearm he advocates what is

not a new discovery, but is certainly not in wide use, namely the posterior straight splint. He says:—

"Any one who studies a forearm will see that when the hand and finger are extended, the dorsal surface is almost an accurate plane, while the ventral surface is very uneven. Arguing from this, I thought it well to follow the apparent hint of nature, and to use this surface for my splints. I soon found that I could treat injuries of the forearm and hand requiring a splint very successfully with a thin, straight splint, applied in the way just described. And I may say that I have found it much easier to prevent stiffness of the wrist-joint—the bone of fractures at the lower end of the radius—by this than by the time-honored Bond's splint, which I have not used for several years. With the Bond's splint I have, in former years, had much trouble from stiffness, and seen much trouble when it has been used by others, because, while the position of the hand seems to be favorable to motion, I have not found it really so, but that the patient's fingers are either bound to it too firmly, or they themselves clasp the block so constantly and so rigidly, in spite of all injunctions to the contrary, as to tend to stiffening of all the joints involved. I need scarcely add to what I have already said any further arguments as to the advantage of the posterior splint in the way of lightness and the facility it affords when used in the way I suggest for examining the seat of injury without disturbing it. The Bond's splint, on the other hand, as frequently applied, is heavy, hot, more or less painful, and troublesome to remove for subsequent examination."

### ARISTOTLE'S IDEAS OF AN ELEPHANT.

F. A. FERNALD, in the *Popular Science Monthly* for April, questions how far Cuvier's statement that "everywhere Aristotle observes facts with attention" is true. In describing the elephant, Aristotle tells many things correctly, but some very incorrectly, so that it is a question whether he ever saw this animal in his life. He affirms that it has no nails on its toes, though he correctly refers to the toes, which are scarcely distinguished. The nails of the elephant are one of the "points" which the natives of India always regarded as marks of a well-bred animal, and are usually conspicuous. Let us take another point, the "gray-headed error" that the elephant has no joints. Aristotle says: "The elephant is not so constructed as to be unable to sit down and bend his legs, as some persons have said, but from his great weight he is unable to bend them on both sides at once, but leans either to the right side or the left, and sleeps in this position." That is to say, the elephant, having bent one foreleg, cannot then bend the other so as to kneel with both, which is contrary to fact. Although in this passage Aristotle demolishes the absurd statement that the elephant has no knee-joints, yet, in his treatise on the *Progressive Motions of Animals*, he seems to leave the matter in doubt. After showing that without infection there can be no progression, he says: "Progression, however, is possible without infection of the leg, in the same manner as

infants creep; and there is an ancient story of this kind about elephants, which is not true, for such animals move because inflection takes place in their shoulder-blades or hips." The existence of animals without knees is again supposed by this remark: "Since the members are equal, inflection must be made in the knee, or in some joint, if the animal that walks is destitute of knees." If Aristotle had ever seen an elephant move, is it not probable that he would have spoken more decidedly and correctly on these points? But the most astonishing assertion is that "the elephant cannot swim on account of the weight of its body"!

#### ST. JOHN'S HOSPITAL, LOWELL, MASS.

The eighteenth report of this institution has reached us, and shows a prosperous year, during which extensive improvements have been made. These improvements have enhanced the benefits and conveniences of the hospital and placed it on a par with first-class institutions of a similar nature in other cities. A new wing, which furnishes ample and much-needed accommodations for the attendant Sisters, has been occupied. In the spacious basement is located the bakery, a large refrigerator, and the servants' refectory. The first floor is occupied by the kitchen, an apartment fitted with the latest and most approved apparatus for cooking, the living-rooms of the Sisters, and the pharmacy. The latter is finely appointed, and is well stocked with medicines, surgical appliances, and the utensils required for the manufacture of tinctures, etc. We notice as a somewhat novel fact that this department is in charge of a Sister who is an experienced pharmacist. On the second floor are the Sisters' infirmary, dormitories, and the chapel. The third floor is also divided into dormitories. The building is provided with all modern conveniences; the sanitary accessories are perfect, and the apartments are high-studded, light, and airy.

The old Livermore house, formerly occupied by the officers and the Sisters' apartments, has been entirely renovated, and furnishes comfortable quarters for the aged inmates and chronic cases formerly located in the upper story of the main building. It is heated by steam, furnished by an independent boiler in the basement. The whole number of patients treated during the year was 319, of which about 30 were surgical cases. The hospital, since its organization in 1867, has treated 1,280 patients.

inspector describes the various fallacies proceeding from too implicit reliance upon the lactometer and cremometer and describes at some length the method which he has used, — a modification of the Wanklyn method.

We note as of special interest the statement of the inspector that only about a quarter of the whole amount of the various substitutes for butter sold in the markets are so labeled as to indicate their true character.

Various suggestions are made by the writer of the report, one of them of a method which he believes would secure to the residents of the city the delivery of their milk-supply on the average twenty-four hours earlier than at present. For this, as well as for suggestions as to the examination of milk by the consumer himself, our readers are referred to the article itself.

#### A NORTHERN MEMORIAL TO SOUTHERN HEROISM.

A MEMORIAL window has recently been placed in St. Peter's Church, Fernandina, Florida, by a physician of Boston, in memory of two of the Southern professional brethren, Drs. Wellford and Herndon, who heroically laid down their lives in the performance of self-elected duty during the epidemic of yellow fever which prevailed in Fernandina in 1877. It was a striking coincidence that these two men, both born in the same city just two years apart, and in the same month, and having volunteered their services, reached Fernandina in the midst of the epidemic on the same day, and that their deaths also occurred the same day.

The memorial is a graceful tribute from a Northern man to his Southern associates who died in a noble cause. In the lower part of the window an illuminated tablet has the following inscription:

FRANCIS PRESTON WELLFORD, M.D.,

Born in Fredericksburg, Va.,  
Sept. 12, 1829.

JAMES CARMICHAEL HERNDON, M.D.,

Born in Fredericksburg, Va.,  
Sept. 22, 1831.

Died in the faithful discharge of their duty,  
at Fernandina, Florida, Oct. 18, 1877.

To whose memory, in grateful recognition of their noble lives and heroic death, this window is dedicated by a New England member of the profession which they so much honored and adorned.

"Greater love hath no man than this, that a man lay down his life for his friends."

#### REPORT OF THE MILK INSPECTOR OF THE CITY OF BOSTON, 1881-85.

This official, whose duties are of such importance to the well-being of the citizens, has just made his twenty-sixth annual report. It covers not only the subject of the dairy products, but vinegar also, which has recently been added to the commodities coming under this supervision. In the matter of milk the inspector made 4,272 analyses and found it necessary to give warning in about a thousand instances. The warnings were so promptly heeded, however, that only 12 cases were entered for prosecution. The

#### HYPNOTIC CHICAGO.

The profession in Chicago have had a curious experience. A well-known member of the Chicago Medical Society read before it a lecture on mesmerism, or "hypnotism," as the modern fashionable word is, and illustrated it with a living example. The members were profoundly impressed, and an interesting and learned discussion followed. But some one of them of an investigating turn of mind pursued the subject further, and discovered that the "able paper" was largely cribbed from an encyclopedia, and that the subject was what they call in

that enlightened metropolis a "horse," in other words, one who hires himself out to professional mesmerists for exhibitions. These "horses" must have a hard time. They submit to having pins thrust in their flesh, red pepper put in their eyes without wincing, and pretend that they believe themselves to be George Washington or Daniel Webster at the wink of the mesmerist. It appears to be quite an avocation in Chicago, a city which is nothing if not progressive.

The result of it is that there is not a man left in Chicago who has faith in any variety of ism whatever, and no energetic young doctor out there eases aught for psychical research, but devotes his undivided attention to patients on the avenues, with an occasional dip into fall wheat and mess pork. To use one of their own expressions, it will be a cold day when the next mesmerist catches the Chicago profession napping. — *Medical and Surgical Reporter.*

## REPORTED MORTALITY FOR THE WEEK ENDING MAY 9, 1885.

Deaths reported 2,676; under five years of age 797; principal infectious diseases (smallpox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrheal diseases) 363; lung diseases 401; consumption 389; diphtheria and croup 129; diarrheal diseases 51; measles 52; scarlet fever 18; typhoid fever 27; cerebro-spinal meningitis 15; malarial fevers 13; putrefreral fever 12; erysipelas 11; whooping-cough eight. From diarrheal diseases, New York 18, Brooklyn nine, Philadelphia five, Boston and Cincinnati four each, St. Louis three, Baltimore, District of Columbia, and Charleston two each, Providence, Lawrence, Springfield, and Holyoke one each. From typhoid fever, Philadelphia eight, New York five, St. Louis four, Boston two, Brooklyn, Cincinnati, Buffalo, Providence, Nashville, Charleston, Lowell, and Holyoke one each. From cerebro-spinal meningitis, New York seven, Philadelphia and Cincinnati two each, Boston, Baltimore, Buffalo, and Fall River one each. From malarial fevers, New York four, Philadelphia and St. Louis two each, Brooklyn, Baltimore, Buffalo, District of Columbia, and Charleston one each. From putrefreral fever, St. Louis four, Brooklyn and Philadelphia two each, Buffalo, Nashville, and Worcester one each. From erysipelas, Philadelphia three, New York and Nashville two each.

Cases reported in Boston: measles 78, scarlet fever 30, diphtheria 28, typhoid fever five, and smallpox one.

In 112 cities and towns of Massachusetts, with an estimated population of 1,110,157 (estimated population of the State 1,955,101), the total death-rate for the week was 17.33, against 19.73 and 19.00 for the preceding two weeks.

In the 28 greatest towns of England and Wales, with an estimated population of 8,906,416, for the week ending Saturday, April 26th, the death-rate was 23.4. Deaths reported 3,991; infants under one year of age 338; acute diseases of the respiratory organs (London) 281, measles 218, whooping-cough 127, diarrheal diseases 45, fever 10, scarlet fever 22, diphtheria 25, smallpox (London 39, Bristol, Liverpool, and Manchester one each) 12. The death-rates ranged from 0.5 in Derby to 35.5 in Newcastle-on-Tyne; Birkenhead 21.9; Birmingham 18.8; Bradford 20.2; Liverpool 20.2; London 22.3; Manchester 30.1; Nottingham 24.2; Sheffield 23.9. In Edinburgh 18.9; Glasgow 27.2; Dublin 21.0.

For the week ending April 25th in the Swiss towns there were 32 deaths from consumption, 110 from diseases 35, diarrheal diseases 11, diphtheria and croup seven, putrefreral fever four, erysipelas and typhoid fever each three, smallpox, and measles each two, scarlet fever one.

The death-rates were at Geneva 15.2; Zurich 23.8; Basle 23.1; Berne 28.1.

The meteorological record for the week ending May 9th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending: Saturday, May 2, 1885.	Barom- eter.	Thermometer.				Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

# OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MED- ICAL DEPARTMENT, U. S. ARMY, FROM MAY 9, 1885, TO MAY 15, 1885.

A BOARD of medical officers, to consist of A. K. SMITH, lieutenant-colonel and surgeon, J. C. G. HAYFISSETT, major and surgeon, JAMES P. KIMBALL, captain and assistant surgeon, appointed to assemble at United States Military Academy, West Point, N. Y., on June 1, 1885, to examine into the physical qualifications of the members of the graduating class and the candidates for admission to the Academy. S. O. 106, A. G. O., May 9, 1885.

McKEE, JAMES C., major and surgeon. Sick leave of absence still further extended four months on surgeon's certificate of disability. S. O. 105, A. G. O., May 8, 1885.

## SOCIETY NOTICES.

MASSACHUSETTS MEDICAL SOCIETY. ONE HUNDRED AND FOURTH ANNIVERSARY.—The Annual Meeting will be held at 9 o'clock A.M., Wednesday, June 10, 1885, in Huntington Hall, at the Institute of Technology, Boylston Street (between Berkeley and Clarendon), Boston. The usual arrangements have been made for the preceding day, Tuesday, June 9th. By order of the President, FRANCIS W. GOSS, Recording Secretary, Roxbury, May 11, 1885.

Tuesday, June 9, 1885. 10 o'clock A.M. The Fellows of the Society are invited to visit the Massachusetts General Hospital, on Harrison Street, the Boston City Hospital, on Harrison Avenue, and the Children's Hospital, on Huntington Avenue.

12 o'clock M. Meeting in Huntington Hall. Papers will be read as follows: "The Pathogenesis of Certain Affections of the Skin," by George N. Tilden, M.D., of Boston. "Concomitant Marriages: their Effect upon Offspring," by Charles F. Willington, M.D., of Roxbury. "Labor complicated with Fibroids," by James R. Chadwick, M.D., of Boston. Adjournment at 2 o'clock.

3 o'clock P.M. "The Climatic Treatment of Phtisis," by Harold Williams, M.D., of Boston. "How a Lesion of the Brain results in that Disturbance of Consciousness known as Aphasia," by Morton H. Prince, M.D., of Boston. "The Relation of Insanity to certain Nervous Affections," by Henry R. Stehman, of Rosindale.

Exhibits.—During Tuesday and Wednesday, at the Institute of Technology, there will be an Exhibit of Electrical Apparatus. There will also be an Exhibit of New and Original Apparatus.

Wednesday, June 10, 1885. 9 o'clock A.M. The One Hundred and Fourth Annual Meeting. (1) Secretary's Report and Report. (2) Treasurer's Report. (3) Reports of Committees, etc. (4) Medical Papers and Communications: "Crenation in its Sanitary Aspects," by John O. Marble, M.D., of Worcester. "Diagnosis and Treatment of Oesophagoenteric Positions," by William L. Richardson, M.D., of Boston. "The Influence of Ovarianity on Surgery," by John H. Rogers, M.D., of Boston. Communications from the Reporters of the District Societies. 10 Introduction of Delegates. Intermission of fifteen minutes.

12 o'clock M. The Annual Discourse, by Franklin K. Packard, M.D., of Pittsfield. The hall doors will remain closed during the delivery of the discourse.

1 o'clock P.M. The Annual Dinner will be served in the Skating Rink, on Clarendon Street, near Boylston, to which place the Fellows, called to order of seniority, will walk in procession. No person will be admitted to the dinner without a ticket. The dinner ticket (not transferable) may be obtained on Tuesday and Wednesday, at the Institute of Technology, by those who have paid their dues for the current year.

Councilors' meetings will be held during the ensuing year at the Medical Library, No. 19 Boylston Place, Boston, as follows: (1) The Annual Meeting, at 7 o'clock P.M., Tuesday, June 9th. (2) A Stated Meeting, at 11 o'clock A.M., Wednesday, October 7th. (3) A Stated Meeting, at 11 o'clock A.M., Wednesday, February 3, 1886.

The Annual Conference of the Censors will be held at 2.30 P.M., Tuesday, June 9, 1885, at No. 19 Boylston Place, Boston.

Censors' Meetings. The Censors for Suffolk District, officiating also for the State Society, will meet in Boston, for the examination of candidates, on Thursday, June 4, 1885, and on the Thursday before the last Saturday of September and of February. But they cannot examine any candidate who is already a resident, or in practice, in any District other than Suffolk. Their meetings will be fully advertised in the *Boston Medical and Surgical Journal*.

In the other Medical Districts the Censors will hold their meetings for the examination of candidates residing in their respective Districts, and none other, at the same place and on the same day as the stated meetings of the District Societies themselves.

OHIO STATE MEDICAL SOCIETY.—The fortieth annual meeting will be held at Dayton, Ohio, June 3, 4, and 5, 1885. The sessions of the Society will be held in the Young Men's Christian Association Building, No. 30 East 4th Street. A competent stenographer will be in attendance. G. A. COLLAMORE, Secretary. TOLEDO, May 9, 1885.

## OBITUARY.

THE death of Dr. John Pierce, of Edgartown, Mass., of which notice has already been made in our columns, removes from that community one who was in every good sense one of its most conspicuous figures, and who socially and professionally held a high position among his fellow-men.

Dr. Pierce was born in Lebanon, Ct., November 25, 1805, but in 1808 became a resident of Monmouth, Me., where he received his academic education. He studied medicine with the late Governor Hubbard, of Maine, and at Bowdoin College, where he was graduated in 1833. He practised his profession in Wales, East Pittston, and Gorham, Me., and in 1836 he removed to Edgartown, where he was in active practice until 1879, and where he has since resided. For eight years he was the surgeon in charge of the United States Marine Hospital at Vineyard Haven, and was a Medical Examiner for Dukes County from the time that office was first established. Since 1840 he was a member of the Massachusetts Medical Society, and held various offices in that organization.

## DEATHS.

DIED. In Roxbury, May 11, 1885, Alfred Clark Downing, M.D., M.M.S.S., formerly of Palmer, aged thirty-six years.

## Original Articles.

## THE SELECTION OF A SUITABLE CLIMATE FOR THE VARIOUS FORMS OF PULMONARY CONSUMPTION.

BY J. HILGARD TYNDALE, M.D., OF NEW YORK.

THE difficulties in the way of a therapeutical basis for the climatic treatment of consumption, and the confusion incident to great diversity of opinion, are due to three facts:—

(1) The comparative recency of careful and correct meteorological observations in most countries.

(2) The lack of a theoretical basis for climate, thereby to build upon our knowledge of the effects of the several constituents of climate (soil and atmosphere) upon the functions of our organism.

(3) The fact that the empirical results of climatic treatment, thus far attained, have not been collected and compared.

That aggregation of pathological manifestations known as pulmonary consumption consists, broadly speaking, of the coexistence and coöperation of inflammation and infection. The acute manifestations of disease are, on the part of inflammation, croupous and catarrhal pneumonia; on the part of infection, acute tuberculosis. Either inflammation or infection usually exists alone at first and then in the chronic form, because lesions of an acute character cannot be classed as phthisis. During the further development of a chronic inflammation of the lung (catarrho-fibroid phthisis or cirrhosis) or the development of a chronic infection (localized tubercular invasion), the brother element will join the existing chronic process, either in a subacute form or as an acute invasion. We have examples of the subacute in cirrhosis being followed by an invasion of tubercle; of chronic tubercular nodes having a subacute zone of inflammatory action set up around them. Examples of the acute are found in a chronic catarrh of the apex being complicated by the superposition of acute tuberculosis; of old tubercular or cheesy nodes suddenly being invaded by an acute catarrh of the bronchioli, or, what is worse, suppurative peribronchitis.

It is in accordance with the length of time intervening between exacerbations of a subacute character that we speak of the *intermittent* and *remittent* forms in which phthisis so often presents itself, and which prolonged intervals give rise to the fallacious doctrine of "self-limitation."

What lesions, in a pathological sense, are brought about by this coöperation of chronic inflammation in the lung and infectious invasion?

(1) Local lesions of superficial inflammation; of condensation, or excavation, of lung tissue.

(2) General septicæmia, chronic or acute blood-poisoning, brought about by autoinfection or by invasion from without; and as a combined result of both we have:—

(3) An anæmic, flabby, and enfeebled condition of the two great *internal muscles*: the heart and diaphragm, the muscles of circulation and respiration.

(1) An enfeebled digestion and assimilation, nutrition not only not up to the requirement of furnishing material for repair, but failing to keep pace

with progressive destruction and infection. From this follows an interference with sanguification, aided by continuous poisoning of the fluids, in which of course the nervous system suffers. All these factors together produce what is collectively termed malnutrition.

We pass now from the actual damage done to an endeavor to classify the various forms in which phthisis presents itself into a few practical heads, which will cover every case which presents itself to climatic treatment. This division is one simply governed by the lung lesion on the one hand and the existing general health on the other: the local and general condition.

Both the normally robust and the hereditarily vulnerable, who are subjected at times to exposure, may be found to suffer from the following conditions:—

(1) Superficial inflammatory processes of the air-passages, of not over eight to ten weeks' standing, with a lowered general condition, said general condition being the direct cause of, and keeping up, the inflammatory process, a fact which explains its persistency as to time and superficiality as to intensity; the functional disturbance of mucous membrane as yet accompanied only by slight *organic* change, such as involves the bronchial submucous tissue.

(2) Slowly progressive *cavities* and *infiltrations*; the result of excavation on the one hand and of condensation on the other. Fever, usually of an intermittent type.

(3) Acute or subacute exacerbations of *inflammations* or *invasions of infection*, supervening after an intermission or remitting upon either of the conditions of the first or second classes named above. Fever usually of a remittent type.

(4) The so-called "third stage": the only difference between it and the preceding one consisting in a *continuity* of action of the fresh inflammatory or tubercular invasion ending only with the death of the patient. Fever always of a continuous type.

Climate is a collective term, used to express the combination of various stable elements of *soil* and *atmosphere* with others more shifting. The meteorological conditions are an ever-shifting panorama of atmospheric elements within certain known limits.

We have seen that all detrimental elements of soil and water do harm by being diffused in the atmosphere which surrounds us. This atmosphere concerns us and our well-being in three different ways: its *pressure* upon the surface of our bodies; its *inhalation* into the lungs, plus the matters suspended in it; and the *stability* of its temperature. Therefore the constituents of climate which concern us are:—

(1) Atmospheric pressure, lessened at elevations and also by decrease of atmospheric moisture, ascertained by the *barometer*.

(2) The quantity of moisture in the atmosphere, ascertained by the *hygrometer*.

(3) The stability of temperature (no matter whether hot or cold) of the material we have to breathe, and which our sensations have to deal with. These facts are ascertained by the *thermometer*.

It will be perceived, then, that the above three constituents of climate represent the all-important

questions of *elevation, dryness, and equability* of temperature. The other constituents of climate are not only the outcome of the combination of two of the above, but are to be considered as natural accompaniments of elevation, dryness, and equability and not as separate elements in the choice of climate. These others are:—

(a) Sunshine, with its qualities of *abundance and intensity*; dependent upon pressure and humidity; inasmuch as lessened pressure at elevations and comparative absence of humidity create a purity and rarity of the atmosphere, which admits of an unobstructed passage of the sun's rays—the so-called "diathermancy" of the atmosphere. The number of clear and fair days in a month or year, as against the cloudy or rainy ones, represents the relative abundance of sunshine—its *quantity*,—a factor common to both dry and equable climates. Intensity of sunlight, on the contrary, represents the *quality* of sunlight and is found only in connection with dryness and elevation.

(b) Winds. The movements of the atmospheric ocean, dependent upon pressure and temperature, causing air when heated and not subjected to great pressure to rise and be replaced by the rushing in of colder air either horizontally, as across planes, or vertically, as down the mountain-side. We note here, as in all else, time and intensity, that is, frequency and velocity of winds, as well as the points of compass from which they blow.

(c) Electricity, dependent upon humidity and temperature; a certain degree of humidity being required to form clouds and certain differences of temperature to bring about atmospheric disturbances. Quality and tension of electricity are interesting features, but as yet we know nothing positive about their effects.

Out of the relations of these three last elements to the first result:—

(a) The production of ozone, of the intensity and utility of the antiseptic qualities of which we know as yet nothing relating to the human organism.

(b) Precipitation of rain, hail, and snow—a phenomenon having no direct bearing upon our organism.

(c) Organic and mechanical admixtures of the air previously referred to. Moisture is the only legitimate suspension in the air, and the reason why the organic and mechanic are not accorded equal importance is that they do not figure so extensively and permanently as moisture. *Moisture in excess* of the average, whether inherent in the soil or large bodies of water, has been proved to be the main *direct* cause of pulmonary consumption.

What are the climatic conditions under which the average human being can flourish? In an atmosphere floating over land or water, which does not furnish abnormal contaminations of the air: an atmosphere in which the pressure of the air column, the degree of moisture and the temperature of the air-mass undergo changes among each other *within reasonable limits, as to time and intensity*—changes which are called "atmospheric variations": the disturbances of health, whether of inflammation or infection, being dependent upon the frequency and intensity with which the usual equilibrium of these constituents is thrown out of a balance many points removed from what constitutes the usual average

variation in a given climate. The barometric, hygrometric, and thermometric conditions may undergo changes out of the usual channel, both as to *time and intensity*. A falling barometer, excessive moisture, and a falling thermometer may either occur suddenly, or with great intensity, or both; two of these conditions frequently occur simultaneously in this climate, for instance. It has been shown that epidemics of inflammatory conditions, such as we have had in the past winter, occur in exact proportion to the number of factors concerned, as well as the suddenness and intensity of the occurrence.<sup>1</sup>

These, then, are the combined disturbances which produce inflammation in relatively well persons and this accords with the statistics of the frequency of active inflammatory conditions of the respiratory mucous membrane in cold climates. What will the disturbances of pressure, moisture, and temperature do in tropical climates? The result is inflammation of an asthenic, stagnant form, with a tendency to blood-poisoning. This, too, is borne out by statistics.<sup>2</sup>

Our formula therefore reads: (1) The sudden or persistent disturbances of climatic constituents in countries where a *cold* temperature predominates result in acute *inflammation* of the lung in those of average health; in catarrhal (low-grade) inflammation in the vulnerable.

(2) The sudden or persistent disturbances of climate where *heat* predominates result in venous stagnation and embolism, in the tubercular form of phthisis and its various phases of *infection*.

With this knowledge before us, we are entitled to ask ourselves, Where shall our consumptives go? A superficial knowledge of the subject would lead us to believe that to determine where to send a patient should be governed by whichever element of disease—inflammation or infection—predominates. To a certain extent this is possible, but in the majority of cases these pathological factors are so harmoniously blended as to nullify such efforts. The teaching of Broussais of old, and Loomis and Flint of to-day, in fact, is: to be governed by the subjective symptoms of the patient, by his sensations and not by the objective physical find. This is substituting *degree* of temperature (warmth or cold) for the true attributes of climate: dryness, elevation, and equability.

If we should decide primarily for high altitude, we make sure of four desirable elements:—

(1) Constantly reduced pressure of the air-column.

(2) Equally constant dryness.

(3) Sunlight, abundant as to quantity and intense as to quality.

(4) A mean between excessive heat and cold,—a cool atmosphere.

What is conspicuously absent is equability of temperature, and this constitutes the main drawback of high-altitude climates in the temperate zone.

The same number and combination of requisite

therapeutic elements can be found nowhere else than at inland altitudes.

Having thus secured our main basis, we turn next to more exact individualization and find, perhaps, a "vulnerable" patient, whose objective symptoms would determine us to send him to an altitude, but in whom the subjective symptoms are very prominent, so that his shivering and shivering tendencies, even in moderately cool weather, make his *sensations* our first duty to consider. This calls for equability of temperature. But should his irritability be allayed by an equable climate, he should seek altitudes, and why? Because equability presupposes moisture and the greater the equability (at sea-level), the greater the moisture. Even in a choice of climate, equability should be subordinated to dryness, by preferring *reasonable equability with moderate moisture* to great equability with excessive moisture. But we have shown that dryness with coolness and a reduced air-pressure are the prime requisites for the average case. And what do we expect these constituents of reduced pressure and dryness to do? Let us recall the actual lesion in an average case of phthisis. What gross lesions do we find in a typical case?

(a) Local destructive processes in the lung.

(b) General septicæmia.

(c) Emphyseal and flabby heart and diaphragm.

We expect of dryness that it will cause a gradual shrinkage and dessication of matter devoid of life, of necrosed lung tissue. This is mainly accomplished by uniform water abstraction, that equalizer of our circulation, relieving stagnation. "The quantity of moisture in the air affects the rate of evaporation from the lungs and skin. Watery vapor, we know, abstracts an undue amount of heat from the respiratory tract, and gives rise to catarrhs, coughs, and perhaps inflammations."<sup>3</sup> This ready conduction of heat in a damp atmosphere produces excessive cooling of the skin and the upper portions of the respiratory tract. In the skin this results in an undue abstraction of heat and, of course, a retardation of normal evaporation of moisture carrying effete matter.

We expect of reduced pressure (aided by this relief from stagnatory processes) that it will call forth renewed activity of the circulation and respiration; at first only functional, but followed by organic changes in the heart and lungs approaching the norm. What proof have we of these assertions? In the absence of excessive moisture at altitudes, we may reasonably look for the absence of other contaminations; although the *freedom* from organic germs of rarefied air at altitudes has not been demonstrated. Since Tyndall's well-known experiment with bottled air from the Alps, no proof of absence of organic matter has been brought forward. So far theory. Practically, we have it on the authority of the statistics of Dr. Williams, of London: "Taking collectively all forms and degrees of phthisis, the *dry* climates are the most likely to arrest the disease."<sup>4</sup>

What proof have we of the effects of altitude? First, the truths taught by physiology, enabling us to judge that when such enormous pressure is taken

away from the body, arterial tension is at liberty to reassert itself.<sup>5</sup>

In practice we learn from such sources as Drs. Williams, Hermann Weber, and others that the action of rarefied air at altitudes upon the heart is one of lowering of action and strengthening of impulse; upon the lungs: expansion of the sound tissue and a commensurate widening of the thorax.<sup>6</sup> Dr. C. T. Williams says of altitude effects:<sup>7</sup>

"(1) Quickening of breathing on reaching high altitudes, supplanted by (2) gradual deepening of the respirations. After six weeks to three months, the rate becomes markedly slow and eventually reaches something like the normal, sometimes even less frequent."

Rarefied air at altitudes contains, of course, less oxygen per cubic foot than air at sea-level. Experiments on animals have shown that as long as the percentage of oxygen is not below 14 (21 being normal), the same quantity is taken up into the circulation as when ingredients are in normal proportion. Conversely, Regnault and Reiset have shown that when an *excess* of oxygen is added to air the quantity consumed is not greater. Both as regards the amount of oxygen per cubic foot and respirations necessary to make up for it, the patient accommodates himself to the surrounding circumstances; at first, as we have seen, by increased *functional* labor, which with the *organic* changes of widening of thorax, etc., becomes normal or even subnormal.

Of equability of temperature, as our third constituent, existing as it does with warmth or coolness and moisture, it is the soothing agent to cases of pulmonary irritation or subacute inflammation of the respiratory organs. Equability with *warmth or coolness* is the remedy for cases in which pulmonary irritation and low-grade inflammation are the prominent features. These are the class of cases recruited from the hereditarily scrofulous. This accords with what Dr. Williams says:<sup>8</sup> "A *warm and dry* climate is more successful in the treatment of phthisis of *inflammatory origin* than a warm or cold one." And again: "Warmth and equability of climate are more important than dryness for patients suffering from phthisis of *catarrhal origin*."

The thus far known and established effects of dryness, elevation, and equability having been noticed, let us look for a moment as to what is known of the effects of *cold and heat per se*. Tersely speaking, the effect of cold is a stimulating one, that of heat a sedative one. Stimulation refers to the vascular system; sedation chiefly to the nervous system. Cold increases tonicity of bloodvessels; hence, an active blood-supply to tissues and organs, and a commensurately more rapid waste and repair. "Increased oxidation of tissue is demonstrated by the greatly increased quantity of carbonic acid thrown off by the lungs on exposure to cold." (Kinger.)

<sup>8</sup> Dumas' Platz and the Effects of High Altitude. By Alfred Wies, M.D. Jena.

<sup>9</sup> Op. cit.

Heat relaxes the contractility of bloodvessels, and promotes active perspiration and corresponding relaxation, amounting to depression. A moderate amount of depression, however, is a sedative effect upon the sensations, and thus it is that when coupled to moisture the relaxing influence upon dry respiratory passages has a soothing effect.

In determining the proper climate for a consumptive, the resisting power of the patient to cold should decide between choosing warmth or coolness. Coolness he may have with dryness and elevation. Warmth he must seek in company with equability. Dryness and elevation restore tonicity to the vascular system. Equability acts as a sedative to the nervous system.

In the temperate zone inland elevation and dryness furnish to the sensations coolness in summer and cold in winter. Equability furnishes heat in summer and warmth or coolness in winter.

The above is a crude outline of the principles underlying the choice of climate for consumptives. Let us now apply them to daily practice. You have a patient before you suffering from one of the forms of consumption:—

(1) His local trouble is either in the nature of an *exacerbation* (loss of substance) or *infiltration* with shrinkage (contraction of substance).

(2) His general condition was either originally good or hereditarily vulnerable.

The features of local and general condition being established, we proceed to examine:—

(a) The heart; its *force* of impulse and *frequency*, which are to be considered in inverse ratio to each other. Force and slowness as “strong”; the “medium” of both, and feebleness of impulse and frequency of action as “feeble.”

(b) The sensibility of the skin and mucous membranes of the patient to extremes of temperature—heat or cold.

*The condition of the vascular system is the chief objective symptom.*

*The condition of the nervous system is the chief subjective symptom.*

The sum total of the result of the examination of the local process, general condition, vascular and nervous systems, forms the basis for our choice of climate. The therapeutic elements of climate given us are: dryness, equability, and elevation, with their accompanying lesser constituents (sunlight, etc.). In addition to these we have warmth and coolness to choose from and extremes of heat and cold to avoid, in order to suit individual sensations. Next remember two maxims:—

(1) That it is your aim to send the patient, if possible, to an altitude; the choice of low, medium, or high altitude to be governed by the corresponding condition of the heart. Feeble and frequent to low; medium to medium; forcible and slow to high altitude.

(2) That sensations should be made the determining feature only if *connected* with recent low-grade inflammation (subacute) or tendency to hæmorrhage (acute).

Do not pay too much attention to the lung process. Two thirds of the lung surface suffice to live within the limits of restricted vitality. The important factors are the vascular and nervous sys-

tems, from the examination of which we get an idea of what we call the “utility” and “resisting power.”

To show how easy it is now to determine the proper climate in given cases, let us glance once more at the various pathological conditions. We have:—

(1) Superficial catarrhal conditions, largely dependent upon the general condition.

(2) Cavities and infiltrations, occurring both in the originally robust, and as sluggish processes in the vulnerable.

(3) An acute exacerbation of either condition.

(4) The colliquative stage, including acute tuberculosis.

The colliquative-stage patients should remain at home. This, however, needs qualification. The acute exacerbations, namely, should likewise remain at home, until the fresh attack has been reduced, but should be sent off as soon thereafter as possible. The difference between the exacerbative and the colliquative is largely one of degree, the former occurring intermittently and remittingly; the latter as a continuous process. Should a good intermission occur, third stages may sometimes be sent off.

The superficial are to be treated for their cause, the general condition, and this can be done on sea or land: a long sea-voyage; sojourn in the mountains; change from city to country.

This leaves us with cavities and infiltrations in the robust and vulnerable and their many intermediate shadings, as between the constituents of dryness, elevation, and equability. The best way to remember what to do is to fix the relative value of these agencies. This order is: Dryness first, equability next, and elevation third. Dryness then is your first choice; the heart's action will determine the altitude (though, if in doubt, with a good medium altitude); equability is desirable, but as it is incompatible with dryness, is to be chosen as prime prescription only when decided irritation and very recent inflammation are the leading features.

Next let the patient state whether he feels best, generally speaking, in warm or cold weather. If warm, and elevation has been decided upon (medium or high), choose a medium or high altitude in a *southern latitude*. If cold be his choice, and elevation has been decided upon, choose a medium or high altitude in a *more northern latitude*.

If warmth agrees best with the patient, and equability of temperature has been decided upon, choose a southern latitude not too remote from the seacoast; but sacrifice a few degrees of equability for a less percentage of moisture.

If coolness is the patient's favorite temperature, and equability has been decided upon, choose inland, in a southerly latitude (Aiken, S. C., Thomasville, Ga.). In either of the above cases, the climax of careful attention will be reached by selecting a southerly latitude in the winter and a northerly one in summer.

(To be concluded.)

—*Doctor*: “It is nothing but an attack of dyspepsia.” *Wife*: “And what does that come from, doctor?” *Doctor*: “That comes from the Greek, madam.”

**TWO ATTACKS OF ASTHENIC PNEUMONIA:  
THE FIRST FOLLOWED BY PAROTITIS;  
THE SECOND BY TYPHOID SYMPTOMS.**

BY JAMES B. AYER, M.D.

Mr. J., druggist, though not robust, was in good health and in active business from the time he left the army up to November 30, 1883. Then (at the age of fifty-five) he was suddenly seized with a chill and sharp pain near the apex of the heart, accompanied by fugitive pains through the body and by pharyngitis and bilious symptoms.

One hour after the chill I was called to him and found the temperature  $100.5^{\circ}$  and pulse 76. The extremities were cold.

On the following day the temperature fell to  $99.5^{\circ}$  and he complained less of pain. He had a jaundiced hue and the urine contained an excess of coloring matter.

Respiration was more rapid than normal, and pneumonia of the asthenic type was suspected.

On the morning of the third day the temperature was  $102.9^{\circ}$ , pulse 90, and respiration 30. There was little pain or discomfort.

On the fourth day consolidation of the lower half of the left lower lobe could be proved. Temperature  $103.5^{\circ}$ ; pulse 120.

Temperature on the fifth day  $102^{\circ}$ ; pulse 100.

The crisis came on the sixth day, the temperature falling to  $98.8^{\circ}$ . He had coughed only a few times and had raised absolutely nothing. The disease had been uneventful, but with the crisis came severe prostration. I have rarely seen a patient so suddenly overcome by a feeling of weakness.

Very marked prostration remained more than one week but did not interfere with resolution. The day after the crisis he complained of dryness of the fauces. He could not open his mouth without suffering pain.

Examination showed swelling of the left parotid gland effacing the lower maxillary line. In the course of four days the parotid had become prominent, extending behind the ear and out on the cheek. It was very hard, involved the skin, and was quite painful.

The temperature at this time was normal; pulse 72. Poultrices afforded more relief than camphorated oil. In a few days the right parotid gland hardened but did not become very prominent.

The left parotid at the end of a fortnight diminished one half, now being the size and shape of a very large plum. From some unknown cause it soon increased in size and remained prominently swollen and hard as stone up to December 18th; then it began slowly to grow smaller. The fauces up to this time had been dry, but began to be moist. At the end of six weeks the left parotid had regained its usual shape and size, but several additional weeks elapsed before both glands had softened.

At no time were there symptoms of abscess or of gangrene.

Mr. J. (though not over robust) attended steadily to his business up to February 12, 1885, fourteen months from the beginning of the first attack, when he was again attacked with pain in the

neighborhood of the left nipple, followed by similar symptoms to those characterizing the former attack. Up to the fourth day the pulse remained in the neighborhood of 90, the temperature fluctuating between  $100^{\circ}$  and  $102.5^{\circ}$ . On the fourth day bronchial respiration could be heard, and on the fifth it was evident that the lower half of the left lower lobe was again consolidated.

On the seventh day resolution began and was nearly completed by the ninth. The temperature had fallen to normal and the tongue was moist. During the whole illness he had not coughed.

Were it not for a flushed condition of the cheeks, and a strange look about his eyes, together with the recollection of the sequelae of the previous attack, I should have felt no uneasiness about his condition.

He was sleeping well, did not complain of headache, no cerebral symptoms were evident, and he began to talk about sitting up in an easy-chair.

At noon of the tenth day he became very restless, incessantly tossing to and fro, and in the evening was constantly delirious.

The pulse-rate was over 120; the temperature could not be taken, but there was no febrile excitement. There was but little heat of the head. He had involuntary evacuations from the bowels and bladder every two or three hours.

The extremities were algid and the condition was that of collapse.

For a moment at a time he could be recalled to seeming consciousness.

Mustard was applied to the chest to the point of blistering, and hot-water bottles applied to the extremities. Constant friction by rubbing was ordered.

These symptoms continued forty-eight hours; during this time there were marked hallucinations of sight. He thought the nurse was the Virgin Mary, and would not allow her to care for him. He saw in imagination his grandchild and other relatives lurking about the room.

At the end of a couple of days he became more quiet, making less effort to get out of bed. At this time he appeared like one in a dream. With great difficulty the extremities were kept from growing cold. Fortunately nourishment and stimulants could be given liberally at frequent intervals.

The temperature fluctuated between  $100^{\circ}$  and  $100.6^{\circ}$ , the pulse between 120 and 130, and the respiration remained in the neighborhood of 15 on the day following the appearance of the delirious symptoms.

The next day found the temperature  $100^{\circ}$ , pulse 120, and respiration 10, while three days later the temperature had fallen to  $96.8^{\circ}$ , the pulse to 100, and respiration to 35.

On the fifth day after the appearance of delirium the mind had become clear. Delusions and hallucinations had disappeared, but there was diarrhoea and a portion of the evacuations were still involuntary.

The temperature at this time was normal. The tongue was covered with a thick coat of brown fur, and he suffered from thirst.

The respirations were rapid (in the neighborhood of 30), but careful examination of the chest showed no sign of pulmonary, nor of cardiac, disease.

<sup>1</sup> Read before the Boston Society for Medical Improvement, May 11, 1885.

On the following day (the sixteenth of the disease) our patient's condition was quite satisfactory, when suddenly the temperature fell below normal and alarming symptoms of collapse again appeared.

For forty-eight hours the temperature remained at 97.8°, then falling to 96.8°, where it remained a couple of days, again descending (on the evening of the twenty-first day from beginning of the attack and eleventh after delirium) to 96°. It remained between 95.9° and 96° till the evening of the twenty-third day.

During these seven days the temperature was taken with the greatest care.

The pulse fluctuated irregularly between 74 and 100, without regard to the temperature, but the respirations gradually became slower.

During this period of seven days the body could with great difficulty be kept from growing very cold and the tongue was dry and furred. A slight movement of the body increased alarmingly the prostration. At times he seemed in an almost lifeless condition.

On the twenty-third day I began to give him fluid extract of coca in three and one-half grain doses, which I thought had an excellent effect, but it was discontinued after the third dose on account of nausea. At this time he began to improve. On the twenty-fifth day the temperature reached 97.8°. The extremities could now be kept warm. The tongue presented a glazed appearance.

He sat up on the thirty-first day for a few moments, went downstairs on the forty-ninth day, and on the seventieth day was able to be out of doors a good portion of the pleasant weather. His temperature at this time was 98.2° only.

Dr. James Ayer saw the patient frequently with me in consultation. By his advice I was encouraged to persistently give brandy, quinine, carbonate of ammonia, and liquid nourishment during the period when there was little prospect of recovery.

Briefly to recapitulate: Our patient, aged fifty-five, strictly temperate, not previously ill for many years, after an insidious attack of pneumonia developed a swelling of the parotid gland the day following crisis in connection with prostration. After a tedious convalescence he returned to business and enjoyed fair health for the period of one year, when a similar attack of pneumonia occurred, followed three days after the crisis by the delirium of cerebral exhaustion and by a severe form of prostration, the symptoms at this time being typhoid in character.

On the sixth day he apparently began to improve, but immediately afterward an alarming state of collapse followed, the temperature falling to 95.9°. This condition of collapse lasted seven days and was followed by a protracted convalescence.

These attacks were examples of the asthenic form of pneumonia. The pulmonary symptoms were mild and insidious, but the prostration was severe and the only source of danger.

Regarding the parotid complication, Jürgensen says: "The reports of the Vienna hospitals mention this complication only six times out of 5,738 cases."

According to Grisolle, patients over sixty are most liable to be attacked. He states that as a rule only

one parotid gland is attacked but in its whole extent. He says that usually this complication is serious, ending in suppuration or gangrene.

Loomis says: "Metastatic parotitis is a rarity. It begins with a catarrh of the duct. The exact cause is obscure. It shows a tendency to suppuration from the beginning and is generally confined to one side."

Pepper says: "Sympathetic or metastatic parotitis is usually unilateral and terminates in suppuration or, much more rarely, in gangrene." He mentions its connection with several diseases, but not with pneumonia. He says that the exciting cause is probably mechanical, excessive dryness connected with fever causes occlusion of the parotid duct with retention of the saliva, suppuration of glandular tissue following. He recognizes that there is a cogent objection to this theory, namely, that dryness of the throat is common in connection with fever, but subsequent parotitis very rare.

Ringer speaks of it as rare, and says that it quickly suppurates. He calls it "parotid bubo."

Jeaffreson, whom he quotes, states that not more than three per cent. of "parotid buboes" resolve.

Flint met five examples of parotid swelling following typhoid and typhus fever, in the winter of 1849-50, but since that time has rarely observed it.

In our case the parotid enlargement was, in my opinion, merely a symptom of debility—as is the case with most glandular swellings.

The Collective Investigation Committee of the British Medical Association, after analyzing the returns of 1,060 cases of pneumonia, report that sequelæ are of very rare occurrence. They report no case of parotitis following pneumonia.

Neither do they find any case of typhoid symptoms resembling those following our patient's second attack.

They do, however, mention one case of congestion of the brain, one of meningitis, and two of acute mania following pneumonia.

It is certain that cerebral exhaustion, combined with a state of general prostration, very rarely gives rise to well-marked typhoid pneumonia following pneumonia, but I cannot give definite figures regarding the frequency.

Typhoid symptoms follow the *asthenic* forms of pneumonia, and are generally fatal in their character.

Owing to the depressing treatment and the rage for venesection which existed in former times, it is said these symptoms were formerly met with more frequently than now.

## THE BASAL PATHOLOGY OF CHOREA.<sup>1</sup>

BY H. C. WOOD, M.D.,

Clinical Professor of Nervous Diseases, in the University of Pennsylvania.

I HAVE come to some definite conclusions concerning the basal pathology of chorea, which I should be glad to communicate to the College, and give the grounds for my belief.

The first point which I wish to make is that the

<sup>1</sup> Communicated to the College of Physicians of Philadelphia, May 6, 1885.

term chorea is simply one which is analogous to the term paralysis, and that the choreic movement is no more the same thing, necessarily, in its basal pathology, than is palsy the same thing in its basal pathology. When we come to study the various forms of disease closely connected with the choreic movements, we find, in the first place, the so-called cerebral or post-hemiplegic chorea, in which, after cerebral palsy, there appear violent convulsions with choreic movements. The seat of this lesion has been assigned by Professor Charcot to the corona radiata, near the lenticular nucleus; and there have been a number of postmortems made which verify this view of its location. There can be no doubt that, in many cases, the lesion is situated in this position; but, on the other hand, it is equally certain that there have been cases of so-called post-hemiplegic chorea in which the lesion has been in the external capsule and in the cortex. We may, therefore, say that this post-hemiplegic chorea is associated with various lesions in the brain, so far as seat is concerned.

Then, again, there has been reported in the *Compt. Rend. Société Biologie*, of Paris, a case of typical post-hemiplegic chorea, having absolutely all the features of organic hemiplegia with chorea, in which the most careful examination made by thoroughly competent persons failed to show any lesion whatsoever of the brain. As there had been a previous history of hysteria, the patient dying of pneumonia, we are forced to the conclusion that we may have post-hemiplegic chorea, which is without lesion, and hysterical in its nature.

When we come to study the more general forms of chorea, leaving out of sight for the present the chorea of childhood, or St. Vitus's dance, we have a chorea which is plainly hysterical; we have the electric chorea of the French, which I believe to be another form of hysterical chorea. We learn that, therefore, we may have a chorea dependent upon lesion of the brain, which also may have various seats, or we may have a chorea independent of any lesion whatsoever in any portion of the nervous system.

When we come to study chorea of childhood, we find that the pathology is perfectly parallel to that of the other forms of chorea. We have a large number of reported cases in which the lesion was evidently capillary embolisms of various portions of the brain, especially of the corpora striata and optic thalami, but also in other portions. We have other cases in which no lesion was to be found. Then we have recent cases, especially reported by Dickinson and Ross, in which serious lesion was found in the spinal cord. The clinical history of chorea in childhood also shows conclusively, to my mind, that it may exist without any organic lesion which can be detected. We have it developing in a moment from emotion, passing off in a few weeks, and affected immensely by a few doses of arsenic or other agencies which would be powerless to affect any severe organic lesion.

So far as the study of the disease in the human subject is concerned, I think that these remarks sum up all that we can reach to, namely, that we may have chorea with various lesions and without lesions.

I have been much interested this winter in studying chorea in the dog. I found that, by offering a small sum of money, I could obtain all the choreic dogs that were needed. I made a careful study of the subject. It has been affirmed that chorea in the dog is different from chorea in the child. The great reason for believing the disease is distinct is that in the dog the movements are chiefly rhythmical, whereas in the child the movements are not usually rhythmical; but I have seen dogs with absolutely a rhythmical chorea, and with all the awkwardness of chorea of children; and, occasionally, we have more or less of the rhythmical type in children. When we come to look at the points of resemblance in the two diseases we find, in the first place, in each case it especially affects the young animal. In the second place, that in each case the disease is associated with a constitutional disorder—distemper in the dog, rheumatism in the child. In the third place, the symptoms are exactly analogous, except that there is more tendency to rhythm in the one than in the other. In the fourth place, the clinical experience of veterinarians and of physicians has led to the same result, namely, that arsenic is the best remedy that is known for chorea in the dog, and that it is the best that is known for chorea in the child.

Unless in the case of a contagious disease, where you can pass the disease from one animal to another, it is manifestly impossible to be perfectly positive that a certain disease in the animal is the same as a certain disease in the child; but, when you find the habit of the affections the same, the symptoms parallel, and the therapy identical, you have as good reasons as can be possibly assigned for believing that the diseases are closely similar. It is, however, not necessary for my present purpose to take it for granted that the diseases are the same.

When I came to study chorea in the dog, the first point to settle was the seat of the lesion. I therefore cut the spinal cord so low as not to interfere with breathing. I found that, invariably, the choreic movement continued after section. Before the section the motions of the front and hind legs were synchronous; that is, a wave of motion starting in the front paw would pass down the hind foot; but after the section this synchronous movement was wanting. The hind legs were completely isolated from the upper portion of the nervous system, and yet continued to exhibit the choreic movements, proof that the movements originated in the spinal cord. I therefore had my search for the seat of lesion narrowed down to a small fragment of nerve tissue. I found that not only did the movements originate in the spinal cord, but that they originated, in all probability, in the motor cells, because when I galvanized the bare sciatic nerve, although the animal exhibited no signs of pain, the movements in the hind leg were at once inhibited. The galvanism of the sciatic nerve could only affect the motor cells. Therefore I came to the conclusion, physiologically, that we had to do here with movement which originated in the motor cells of the spinal cord.

The next step was to examine the cord. Gowers and Sankey found in the cord a peculiar infiltration with leucocytes, and they came to the conclusion

that leucocytal infiltration was the basal pathology of this disorder. Gowers had previously examined a cord without finding this condition. I examined a spinal cord and thought that I had found Gowers's lesion, but I was careful not to say so positively, because I had a suspicion that what was supposed to be a lesion was simply a peculiarity of the dog's cord. When I examined the cords of healthy dogs I found the same leucocytes. I do not say that what I saw was the same as the condition described by Gowers.

When I first examined the cord I perceived nothing wrong beyond what has been noted, but, by-and-by, as I began to study the specimen more and more closely, I found that the motor cells refused to take the carmine and hematoxylin staining as they should do. Then I remembered that I had killed the dog early in the disease. Then I took the cord of a dog which had died of the disease. Under these circumstances the lesion in the motor cells was very marked. They were crumpled up, the processes were gone, and the nuclei had disappeared. They were merely masses of matter, taking very little staining, just enough to show that they were protoplasmic. As I killed dog after dog in different stages, I found that the motor cells were to be noticed in all stages of degeneration. First, the perfect cell, then the cell which stained badly, then one with nuclei disappearing, the margins becoming obscured, the processes dropping off, and opacity occurring; and, finally, the irregular protoplasmic balls. In a few cases I noticed peculiar degeneration, that is, the formation of vacuoles in these cells. A change, then, in ganglionic cells is what I believe to be the basal lesion of chorea.

It so happens that some years ago Putnam, of Boston, studied chorea in the cat. In the first case he found no lesion, but in the second he found the lesion which I have described. The important point is that he found that this lesion pervaded not only the spinal cord, but the whole nervous system. We all know that the choreic movement is only a part of the symptoms of the disease, and that the moral and intellectual part of the child also suffers. I believe that in children we have an altered condition of the ganglionic cells. The reason that no lesion is found early is that the disease is at first functional. It is not necessary that I should call attention to the fact that there is no such thing as functional and organic disease. The line which we draw is a purely arbitrary one; for the moment there is altered function, there is altered protoplasmic change, and when there is altered protoplasmic change, there is altered nutrition, and then organic disease. Our microscopic eye is so blind and gross that it cannot see these fine changes until they become so distinct that we can detect them, and then we say that organic disease exists.

The history of chorea I conceive to be this: Owing to emotional disturbance, some stopping up of various vessels of the brain, or sometimes to the presence of organic disease, now this cause, and now that, there is an altered condition of the ganglionic cells throughout the nerve centres. If the cause is removed, and the altered condition of the nerve cells goes only so far, it remains what we call a functional disease. If it goes so far that the

cells show alteration, we have an organic disease of the nervous system.

The capillary emboli, the clots, the tumors, and the various gross lesions which have been found in chorea, are not, in my opinion, the basal lesion, but the cause which produces these changes in the cells which are at the bottom of the choreic movements.

[A number of micro-photographs were exhibited.]

## RECENT PROGRESS IN PATHOLOGY AND PATHOLOGICAL ANATOMY.

BY WILLIAM F. WHITNEY, M.D.

### A CONTRIBUTION TO THE PATHOLOGY OF PHOSPHORUS POISONING.

VON STARCK<sup>1</sup> has carefully compared a number of cases with especial reference to the statement of Perls that the distinction between fatty degeneration and infiltration of the liver lies in the way in which the normal constituents are replaced by fat. In the first case it is solid constituents, while in the second it is the water.

Comparative analyses were made on the organs coming from cases of phosphorus poisoning and from the so-called acute (idiopathic) atrophy of the liver.

In the last-named disease there was found a marked increase in the amount of water, a moderate accumulation of fat, and corresponding to this a decrease in its solid parts. In the former, on the other hand, the water was decreased, the fat enormously increased, and the solids somewhat decreased but not proportionately. The only chance of confounding the two arose in those extremely rare cases of poisoning in very much emaciated individuals, and when death did not occur until the tenth or twelfth day.

The question naturally arises, from whence comes this large quantity of fat in so short a time? If it is assumed that with the exception of the amount normally present, it is all produced by a destruction of the albuminous constituents, then the amount thus used up must be very great. And this would be shown by a marked increase in the excretion of nitrogen, which, however, is not the case. Leberdeff<sup>2</sup> has also come to a similar conclusion against the assumption that the accumulation of fat in phosphorus poisoning is to be referred to the destruction of albumen. He goes too far, however, in the opinion of the author, in stating that all the fat in such pathological conditions is derived from that already prepared in the body. His experiments upon dogs in relation to this are of the utmost importance and need careful repetition. He fed the animals, which had been emaciated by starvation, upon linsed oil, tallow, and lard, then poisoned them with phosphorus. The examination of the liver showed that the greater part of the fat was of a different character from that normal to the dog. From this the fact of fatty infiltration was directly proved. To deny the origin of fat from albumen as Leberdeff does is not to be allowed. But we can agree with him in attributing the greater part to an

<sup>1</sup> *Deutsch. Arch. f. Klin. Med.*, vol. lxxx, p. 181.

<sup>2</sup> *Philolog. Arch.*, vol. xxxi, p. 15.

infiltration, which comes mostly from that already prepared in the body. In confirmation of this would stand the fact that in a very thin person who has died from this poison there is found a small and not an enlarged fatty liver. From all this he concludes that Perls's definition of the distinction does not apply without further restriction to the results obtained from analyses and that these are only of relative worth.

He further gives the history of a case of recovery in which an increase of the excretion of nitrogen had been noticed with a slight icterus. This had hitherto only been found in fatal cases.

His conclusions are summed up as follows:—

(1) Even in a case terminating in recovery, an increased secretion of urea may be found on the fourth to sixth day, without any apparent increase in the size of the liver.

(2) From the analysis of the fat and water found in the liver it appears that the first has originated in other places and been mostly infiltrated.

(3) Since phosphorus can remain in the stomach and intestines until the end of the second day (see his case in the original), an evacuating treatment is indicated even at that time.

(4) From the estimate of fat and water in the liver of acute atrophy (idiopathic) the origin of fat from albumen is to be assumed.

#### THE HYALINE (WAXY) DEGENERATION OF THE SMOOTH MUSCULAR FIBRES.

According to Von Recklinghausen there is a degeneration of smooth muscular fibres identical with that first described by Zenker for striated muscles. In consequence of this Beneke<sup>3</sup> first instituted some experiments on these last in order to study the process in its simplest aspect. For this purpose he watched the changes which took place in a frog's muscle when placed in a weak solution of common salt. From this it seemed probable that two distinct and diametrically opposed processes went on side by side. One consisted in the washing out of an albuminous substance soluble in the salt solution and the other in the precipitation of an insoluble one. The greater the amount of fluid present, the faster the degeneration progressed. The sequence of events was as follows: The solution permeated the muscle and freed the soluble albuminate from its anatomical arrangement. Then when the structure was disturbed the insoluble and consequently coagulable bodies ran together into hyaline flakes, which finally changed into the characteristic clumps. If this coagulation had already taken place before the soluble parts were removed (as in rigor mortis, by placing the muscles in distilled water, or by strong faradization) then the changes were greatly modified and went forward much more slowly. The author considers that similar modifications take place after the death of the fibres when this occurs within the living organism, or in wounded fibres which are simply kept wet without additional fluid, as in the case of stumps after amputation. Here the microscopic pictures varied somewhat and although not identical were very closely related to those seen in his experiments.

The hyaline degeneration of the smooth muscle

can be placed by the side of this last, however. In this case there is also a separation of one albuminate which permeates the living cells, and the appearance of another kind in the form of highly glancing balls. But there are some obvious differences. In the striped variety the most marked pictures of degeneration—aside from what occurs in typhoid fever—are seen after the use of the salt solution; while under physiological conditions there is only seen the marks of post-mortem coagulation. In the smooth elements, on the other hand, the hyaline changes are most marked after the undisturbed physiological death of the intact cell within the organism. The salt solution seems to render the production of the most marked examples very difficult and by a relatively large excess of fluid to stop them entirely. A medium amount of moisture is most favorable to their development. Examination of the stomach, intestines, etc., of frogs, rabbits, or cattle gave no reason to believe in the occurrence of a hyaline deposit in living cells.

In man the degeneration was noted very shortly after death in an extreme degree and to a great extent. This was especially the case in the intestines where single cells of the most characteristic type could be met with only a few hours post-mortem. At times the highly refracting masses appeared as large cubical bodies, or as finely plaited threads, or as rods placed transversely, or as spindles laid obliquely, or they assumed half-moon shapes. There does not appear to be any regularity in their arrangement, but they never are seen to fill the entire cell. The unoccupied part is more or less collapsed, and pale. Not infrequently little fat drops are to be made out. As a rule the nuclei are intact; but exceptionally they are invaded in the same way.

In its relation to reagents hyaline acts very variably. From this the author concludes that it is not necessarily a pure substance but can be mixed more or less with other albuminous materials. Acetic, nitric acid and potash in weak solutions make the fresh hyaline unrecognizable, that is, it is dissolved. The development of this substance is therefore impossible in all cells which are rich in acid or alkali. For instance, in cadaveric softening of the stomach, when the gastric juice reaches the muscularis, as well as in the alkaline condition produced in extreme decomposition, or by the action of the intestinal juice on the muscular cells laid bare in ulceration.

This degeneration has essentially the same course in man as in animals. It is the expression of the cell, which may either be local and occur during the death or the life of the individual, or be generally diffused with the death of the whole organism. Its production is dependent upon the method in which the cell dies and the character of the fluid which bathes it. From this point are to be considered the effects of general or local disease on the course of this process. In general anemia the cells appear pale, narrow, and show small hyaline stripes. In a case of acute anemia following placenta previa the uterine tissue was extremely affected, more markedly on account of puerperal hyperplasia of the cells. In inflammation the degree is very varying, most remarkable where a hypertrophy has been called

<sup>3</sup> Fortschritte der Medizin, 1885, p. 179.

forth by chronic inflammation, as, for example, in the stomach or bladder. In general diseases accompanied by fever the conditions vary with the different cases.

Hypertrophied muscle cells in new growths in the neighborhood of the muscularis are found extremely altered. In one case of myelitis, with long-existing paralysis of the bladder and anus, hyaline masses were found but sparingly in the dry muscular wall of the bladder. In the coats of the intestine, on the contrary, they were very numerous, but without any great distinction between the amount found in the sphincter ani interni and other parts of the canal.

#### OBSERVATIONS ON ISCHEMIC MUSCULAR PARALYSIS AND CONTRACTIONS.

It is well known that after the application of a tight bandage on the forearm and hand there sometimes follows paralysis and contraction, which have been regarded as the result of an ischaemia. In the lower extremity this has rarely been observed. Leese<sup>4</sup> has taken this topic for the subject of an inaugural thesis. The phenomena seem to depend upon cutting off the arterial blood supply, while the venous hyperaemia, often associated with this, acts in hastening the beginning of the paralysis. It seems to be in no way associated with a primary injury of the nerves from pressure, but is solely a contraction of inflamed muscles. The primitive fibres die upon being deprived of oxygen for too long a time; their contractile substance coagulates, becomes agglomerated into balls, and is finally absorbed. The contraction which follows is to be looked at as one similar to that of rigor mortis. The occurrence of paralysis and contraction at the same time marks this as not of nervous origin, as well as the fact of the great resistance to any passive motion.

Such cases are not infrequent in the large clinics, the author having met with seven during one winter. In six there was fracture of the fore, or upper, arm, and in one there did not appear to have been any injury. The clinical features were as follows:—

Shortly after the bandage was applied, the hand and fingers, which had been left free, began to swell, and great pain was felt in the entire arm, as well as numbness in the fingers. The symptoms were usually so severe as to cause removal of the bandage in a short time. If this was not done the fingers and hand began to be firmly flexed. The pain still kept on. At the end of twenty-four hours, if the arm was examined, the hand was found to be in a position of moderate contraction, the limb felt brawny and hard, the muscles were so stiff that the patient could not make the slightest movement himself, and any attempt at forced movement of the fingers caused intense pain. Afterward swelling of the included part began, and usually reached its height in from two to eight hours. This gradually receded, giving place to a centric contraction. If the injury was only moderate there was associated with the flexion an inability to move the fingers and hand, dependent upon a true muscular paralysis, as shown by the electric current. An absolute shortening could not be demonstrated.

In the severe cases, however, there was a diminution in the length of the muscles, especially in the flexors of the forearm. When the points of insertion were brought nearer together the fingers could be straightened, but when they were separated by extending the wrist they then assumed the flexed position corresponding to the real shortening of the muscles.

The examination with electricity gave the same result in all cases. On direct irritation by the Faradic current there was not the slightest reaction. The constant current, on the other hand, produced very weak, but still perceptible, contractions. The paralysis was thus clearly of myogenic origin.

These clinical facts have been further controlled by experiment. Frogs and rabbits were used for this purpose. In the former it was possible to produce an ischemic paralysis by passing an elastic ligature round the entire limb, taking care to exclude the sciatic nerve. The process, however, went on with too little energy to compare it with that observed in man. In rabbits, on the other hand, the parallel was very close. One of the posterior extremities was enveloped in a flannel or rubber bandage under moderate pressure, or bound round with a rubber tube at the upper part of the leg. If the circulation was stopped for at least three hours there was a functional disturbance quite analogous to that seen clinically. Directly after the removal of the pressure the limb was found to be paralyzed, the temperature slightly lowered, but the sensibility not essentially diminished. Faradic reaction was always lessened, and in some cases entirely wanting. At the end of twenty-four hours the loss of power still continued, and the temperature appeared higher than that of the other limbs. Swelling was apparent, and reached its highest point in from forty-eight to seventy-two hours. The muscles were very hard to the touch. In from eight to fourteen days the inflammation had entirely subsided, and the paralysis disappeared. After three weeks the leg was entirely well. The nerves showed themselves to be unaffected throughout. The difference in the final result from that observed in man was explained by the fact that the animals were allowed free use of their limbs after the removal of the bandage. If, however, the leg was fixed in a splint for several weeks the paralysis and loss of electrical reaction continued permanent.

Bits of muscle were taken from three patients and from the animals experimented upon and examined microscopically. At the height of the invasion there was a marked accumulation of round cells between the fibres, which were thus widely separated and often destroyed. In the later stages the cells had given place to formed connective tissue, among which were to be found muscular fibres markedly atrophied and devoid of nuclei. The capillaries were also seen to be wanting in nuclei. The number of destroyed and degenerated fibres was greatest in those places where the inflammatory appearances were most expressed, as shown by the great cellular increase. But this varied in different parts of the same muscle.

Regeneration was very rare. A slight improvement was seen after treatment, but entire restitution was found only in the lightest cases. Prophy-

<sup>4</sup> *Zeit. für die klin. Med.*, vol. III, p. 108.

lactic care is all that does any good, and the dangers of the plaster bandage in the typical fracture of the radius are strongly emphasized.

ON THE INFLAMMATORY CHANGES IN THE GLOMERULI,  
AND ON ACUTE NEPHRITIS.

Larghans<sup>5</sup> has written a long article, of which only the results can be noticed here, and which is a confirmation of investigations already published by him. Klebs was the first to show that in many forms of acute nephritis, for example, that following scarlet fever, the glomeruli alone were affected. The author has gone a step further, and shows that the changes which take place in the capsular epithelium and that covering the coil of capillaries of the Malpighian bodies are to be sharply differentiated from those going on inside of the capillaries themselves.

He found in the glomerulus the following changes:

(1) A filling up of the capillaries with a protoplasmic mass rich in nuclei. (2) Desquamation and proliferation of the epithelium covering the glomerulus, associated with emigration of leucocytes. (3) Similar changes in the epithelium of the capsule.

His studies further lead him to consider the normal capillaries of the glomerulus as having the following structure: Their wall consists of two layers, an outer, thicker, homogeneous one, which can well be regarded as a basement membrane, and an internal firmly adherent nuclear layer. The protoplasmic substance of this is extremely firm, and not easy of observation unless thickened pathologically.

He lays great stress on the necessity of the finest manipulation of the specimens, and his own method has been to cut extremely fine sections, from specimens imbedded in celloidin, with Thom's large microtome. The glomeruli naturally fall out of their capsules, and are then allowed to settle to the bottom of a glass, carefully taken up with a pipette, and stained in carmine. The preparations were previously hardened in spirit or osmic acid.

Isolated bodies were also obtained by carefully teasing a bit of kidney, that had been macerated for one or two days in chromate of potash, with very fine needles under a simple microscope.

The author believes that the implication of the stroma is of secondary importance, and that the changes of the glomeruli should have a much more important place than has hitherto been assigned them. His division of the forms of acute nephritis would depend upon the degree to which the tubules and Malpighian bodies were affected, and he distinguishes three classes:—

I. Nephritis with equal disease of the glomeruli and tubes.

(1) Moderate degree. Glomeruli with little swelling of the endothelial lining, slight granular degeneration of the epithelium of convoluted tubules, hyaline casts. Stroma often not perceptibly affected. Usual form in diphtheria.

(2) Middle degree. The endothelial lining of the glomeruli markedly swollen, even to clouding of the capillary wall, but without much effect on the circulation. (Amount of urine normal.) Epithelium of the capsule and glomerulus swollen; a ring of albumen in the capsule. Swelling and advanced

granular degeneration of the epithelium of the cortex. Casts. Stroma swollen and granular. Small foci of cell infiltration.

Pneumonia, typhoid fever, puerperal fever, ulcerative endocarditis.

(3) High degree. Filling of the capillaries of the glomerulus with protoplasm rich in nuclei; circulation impeded, which can cause diminution of the secretion even to complete anuria. Swelling, proliferation, and desquamation of the glomerular and capsular epithelium. Tubules: swelling of the epithelium, with extreme granular degeneration or complete desquamation. Stroma as above or diffusely swollen. Typhus and phlegmone.

II. Nearly pure glomerulo-nephritis. Extreme degree of intracapillary changes in the glomerulus, often with implication of the epithelium covering its loops, more rarely of that on the capsular wall. Slight granular degeneration in the tubules. Stroma unaffected. Scarlet fever, measles.

III. Pronounced or exclusive disease of the tubules.

According to the author's experience this only occurs in the kidney of icterus. The clinical facts of the occurrence first of casts and then of albumen also substantiate this. Further, the accumulation of dark-brown pigment in the cells of the collecting tubes points to their taking part in the secretion of urine, which has been denied by some. Some other soluble poisons, as aloin, cantharidin, chromic acid, and dissolved hamoglobin seem also to act chiefly upon the lining of the tubes.

## Hospital Practice and Clinical Memoranda.

### EMMET'S OPERATION FOR LACERATED CERVIX, UNDER HYDROCHLORATE OF COCAINE.

BY A. GASTON ROETH, M.D., OF BOSTON.

Mrs. A. M., aged thirty-five; multipara; her last child was delivered with forceps, since which time she has complained of leucorrhœa, menorrhagia, and backache. On examination I found a laceration extending from the os externum to the fold of the vagina, on the right side, readily admitting the finger into the cavity of the uterus.

As Emmet's operation for the relief of this condition is always performed under ether, I deem it noteworthy to give my individual experience relative to the value of cocaine in its performance.

With twenty minims of a four per cent. solution of Merk's hydrochlorate I made three hypodermic injections into the cervix, that is, one into each side of the rent, and one at the base of the sulcus. After an interval of five minutes I painted the surfaces which were to be denuded, and shortly afterward began and completed the operation in the usual manner. From the moment of the denudation of the hypertrophied surfaces to the insertion of the last wire suture the patient made no sign of pain.

The quantity of the drug used was a little more than half a drachm. In future I shall always depend on hydrochlorate of cocaine as a substitute for ether in this operation.

## Reports of Societies.

### PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M.D., SECRETARY.

MAY 11, 1885. The President, Dr. F. W. DRAPER, in the chair.

DR. THOMAS DWIGHT called attention to

#### SOME POINTS IN THE PHYSIOLOGY AND PATHOLOGY OF THE NECK AND CHEST, SHOWN BY FROZEN SECTIONS.

showing the actual specimens and also plates. The points to which attention was especially called were: The effect of rotation of the head on the larynx; the relation of the carotid to the sterno-mastoid muscle; the shape of the œsophagus; also the effect of effusions on the lungs and pleura.

Henke has stated that rotation of the head takes place mostly between the atlas and axis, and very little below these bones: that in front of the vertebrae it takes place mostly between the hyoid bone and thyroid cartilage, and but little below the thyroid; also that turning the head draws the sterno-mastoid forward enough to cover the carotid and remove it from the anterior triangle. Dr. Dwight's subject was frozen, lying on its back, with the neck turned as far round as it would go, and bent a little downward. The first section was through the chin, and carried entirely through the neck, and shows a prevertebral space filled with loose cellular tissue, a space through which an abscess can burrow downward. It should be stated that if the parts are relaxed by death before freezing, the relative position may be slightly changed by that cause. In going down the neck the thyroid was found to be rotated as well as the hyoid; the cricoid, too, was much rotated, and the trachea was also curved much to one side. The œsophagus, instead of being flattened from before backward, as is commonly taught, was round, and with a positive cavity during most of its course, though somewhat flattened at its upper end. This is also shown in the plates of Braune. It lay, as usual, somewhat to the left of the trachea, the position which caused Nélaton to propose making the same cut in opening it as in tracheotomy, and then pushing the trachea to the right. The arch of the aorta pushed the œsophagus to the right, that is, in to the middle line. At the bifurcation of the trachea it suddenly became wider to thirty-five millimeters. The aorta and œsophagus wind spirally about each other, as is also shown in the plates of Pirogoff and in Dr. Dwight's own sections of a child. The left subclavian and right axillary arteries were shown in one section, the subclavian resting on the pleura.

A point of clinical interest is that the fissure separating the superior lobe gets to the bottom of the lung before it gets to the front of it, explaining how we may have resonance in front in spite of the presence of consolidation of the lower lobe.

DR. DWIGHT referred also to a paper by Mr. Moxon, in the *Lancet* in January, 1881, on the different effect on the heart of effusions in the right and left pleural cavities. Moxon thought that pressure on the right side of the heart made it smaller by interfering with the entrance of blood, while pressure on the left by making the passage of blood

different from the lungs to the heart tended to dilate it, and give this as a reason why the apex-ventricle is more readily displaced to the right than to the left.

Dr. F. I. KNIGHT asked if Dr. Dwight supposed sudden deaths in pleurisy to be due, as Trousseau believed, to a twist in the vena cava.

Dr. DWIGHT thought it more likely to be that than a twist in the aorta.

Dr. E. G. CUTLER said that he had made one post-mortem in which there was a double twist, the heart from right to left and the apex from left to right. He could not repeat this artificially except from the apex.

Dr. F. H. HOOPER referred to the shape of the œsophagus, which is supposed by Morell Mackenzie to have a greatest transverse diameter.

Dr. DWIGHT said that there is no question but that the greatest diameter is transverse. The mistake is in supposing that the walls lie together. There is a certain lumen.

Dr. DRAPER stated that many medico-legal writers included among the signs of death by drowning the presence of a considerable amount of water in the stomach; the theory being that fluid could enter the stomach by the œsophagus by vital action only, and that the anatomy of the pharynx and œsophagus forbade its penetration to the stomach post-mortem. He asked Dr. Dwight if his observations on the position and anatomy of the œsophagus confirmed that view.

Dr. DWIGHT answered that he had some hesitation in answering absolutely. He would be slow to deny that some water *may* enter, but it is with difficulty. The tongue may fall back so as also to close it.

Dr. J. B. AYER read a paper entitled

#### TWO ATTACKS OF ASTHENIC PNEUMONIA: THE FIRST FOLLOWED BY PAROTITIS; THE SECOND BY TYPHOID SYMPTOMS.

Dr. W. W. WELLINGTON reported the following cases in connection with Dr. Ayer's:—

On the evening of the eighteenth of April I was called to see Miss S., aged fifteen years. Early in the forenoon she had had a severe chill, followed by fever, headache, pain in the right side of the chest and in the back. At the time of visit the pulse was 120, the temperature 101° F., respirations 28, and there was a slight cough.

Next day (19th) pulse 130, temperature 101° F., headache, delirium, cough, pain in the right side, some abdominal pain, and slight diarrhœa. Next day (20th) symptoms the same, with the addition of rusty sputa. No noticeable change in respiratory sounds. Next day (21st) pulse 120, temperature 103° F. Sputa rusty and more abundant. Respiratory sounds normal. Next day (22d) pulse 120, temperature 101°, respirations 36. Evident pneumonia with consolidation of the upper lobe of right lung, with bronchial respiration and bronchophony. Sputa rusty. Next day (23d) pulse 120, temperature 103½° F., respirations 32. Pneumonia extending down right lung. Some diarrhœa. Next day (24th) dullness and bronchial respiration over whole of right lung. On the morning of the next day

(25th) the pulse and temperature had subsided, and, from this time on, the lung improved, dullness gradually passed off, and breathing became better. The pulse was 88, and the temperature 97.8°.

On the evening of the 26th (the twelfth day of the sickness) there was a chill, followed by severe fever, and on the morning of the 27th I found the pulse 120, the temperature 103.8° F., the respirations 20. Patient was feverish and stupid. I supposed the pneumonia had attacked the other lung, but auscultation revealed no change in the breathing. At my evening visit the girl was sitting up in bed, reading the newspaper; the pulse 96 and the temperature 99.5° F. There was no extension of the pneumonia, and the right lung was improving.

The next three days there was each day a slight paroxysm of fever, lasting two or three hours.

May 1st. A.M. pulse 116, temperature 101.8° F., respirations 20. Dull and listless. A slight chill preceded the fever. Slight dullness remained over right shoulder, and a few coarse râles over remainder of right side of chest. In evening, pulse 96, temperature 99.5° F.

May 2d. A.M. Chill and fever. P.M. Feeling well; pulse 88, temperature 98° F., respirations 16.

May 3d. A.M. Chill and fever; pulse 120, temperature 105° F. P.M. Feeling well; pulse 92, temperature 99° F.

May 4th. A.M. Feeling well; pulse 100; temperature 99.1° F. P.M. Chill, fever, and sweating, lasting from 12 M. till 4 P.M.

May 5th. A.M. Pulse 96, temperature 98.5° F. Had slept all night; no pain; good appetite. At 1 P.M. a chill, followed by heat, lasting till 11 P.M. In evening, pulse 120, temperature 105° F.

May 6th. A.M. Pulse 96, temperature 98.5° F. P.M. Fever a little later than yesterday.

May 7th. A slight chill and fever occurred during day. Patient took seventeen grains of quinine.

May 8th. No chill or fever. Eighteen grains of quinine.

May 9th. No chill or fever.

May 10th. Slight chill and fever, followed by sweating. Dull and heavy all day.

May 11th. No paroxysm.

May 12th. No paroxysm; appetite good; feeling well. Recovered without further relapse.

Here was a case of pneumonia which ran its course in about a fortnight. It had two peculiarities: (1) Though the disease was clearly enough pneumonia from the beginning, judging from the constitutional symptoms, yet no sign was discovered by auscultation till the fifth day, when evidence of consolidation was found in the upper lobe of the right lung. Thence it spread down through the whole lung. The disease probably began in the central part of the lung. (2) It first showed itself in the upper lobe, and spread downward, contrary to the usual custom. Such exceptions, however, are not very rare.

But I report this case chiefly on account of its accompaniment. On the eighth day of pneumonia, and about the time it began to decline, a chill occurred, followed by fever, headache, and exhaustion. A similar paroxysm occurred the next day. These paroxysms increased in severity, so that for

several days the pulse rose to 120 and the temperature to 103° and 105° F., falling off in a few hours, the pulse to less than 100 and the temperature to 98° or 99° F. During this time the pneumonia, judging from the physical signs, was declining. There was no local trouble to explain this state of things. Such paroxysms are usually caused by pyæmia or malaria. I am confident there was no pyæmia. Malarial disease seems to be finding its way eastward, and possibly this was one of its visitations.

Quinine was given pretty liberally. Its first effect was to postpone the paroxysms; finally it seemed to stop them. The whole disease lasted twenty-five days.

CASE II. Pneumonia in a man of seventy. On the ninth day convalescence fairly began. Severe epistaxis, for which left nostril was plugged, and which returned two days later, the plug having been out for a day, but being then returned. On the following morning the roof of the mouth and soft palate covered with a gray membranous exudation; throat red and swollen. In the evening the exudation had separated from the roof of the mouth and hung like a curtain. Detached a large piece with scissors. Breath very offensive. Respiration and swallowing difficult. Pulse and temperature nearly normal. There was no constitutional symptom, but the membrane was a week in disappearing. In the course of the week was bleeding once, apparently from the lungs, and the patient became very weak, but rallied with food and stimulant. At the end of three weeks from the beginning of the attack consolidation remained. He left the city, and was said to be well in a few months.

CASE III. A gentleman, aged sixty-eight. He had been unfortunate in business, and probably this in some degree affected his general health. Began to feel sick the day before the first visit. Complained of pain in the back and legs, and also in the lower part of the right chest. Pain on taking a long breath. Pulse 100, temperature 102° F. No chills or cough. Auscultation negative. For the next three days his temperature was 101.6° F.; pain in side continued.

Fifth day. Pain in side continued; friction, with dullness, was for the first time discovered. Respirations 28, pulse 88, temperature 101.5° F.

Eighth day. The pain in side relieved, and pulse and temperature normal. Tongue coated. No appetite. Instead of improving he grew worse. There was no return of fever, but he gained no appetite, grew weaker, and looked pale and haggard. The tongue coated. Slight diarrhœa, which was readily checked, but no pulmonary symptoms.

He grew worse every day. Exhaustion became extreme. He could hardly be raised in bed without fainting. Anorexia was complete. All he prayed for was "to be let alone." Specific gravity of urine was 1012, with a sediment of uric-acid crystals. Later, he had hiccup, occasional involuntary defecations, retention of urine. He died on the seventeenth day of the disease.

The autopsy showed hepatization of upper lobe of right lung and incipient pneumonia of middle lobe; also pleurisy, with effusion of lymph over the lower lobe. Abnormal redness of lining membrane of stomach also existed.

Pleurisy had been discovered antemortem; pneumonia had not; in fact, it had not been suspected. This may be considered gross neglect on my part. I can only say, in extenuation, that the patient had no fever, after its subsidence on the eighth day, until the day before he died, when his pulse went up to 112; he had no chills, no special dyspnea, no expectoration, no cough, nothing, in fact, to indicate pneumonia. The original pain in the side had disappeared with the fever. A careful physical examination would undoubtedly have revealed dullness, etc., but no disease being suspected no examination was made.

Dr. S. L. ABBOT spoke of a case of pneumonia, still under his treatment, which had presented some peculiar features. The patient was a lady over sixty years of age, of marked nervous temperament. After returning home in a horse-car, on the afternoon of the 30th ult., she had severe chills, with pain across the loins, and considerable headache. The following night she slept little on account of pain, which extended up to the lower part of the left chest, and a frequent cough, without expectoration. Respiration was found to be somewhat harsh in the lower half of the left back, where there were a few coarse mucous râles. There had been free perspiration during the night after taking fifteen grains of Dover's powder, at intervals, in five-grain pills. The tongue was moist and nearly clean. Temperature in the morning (May 1st) 103° F. At this time pain in the back was so severe, extending up to the shoulders, that the patient was unable to sit up or turn in bed without crying out. As she had suffered somewhat from rheumatism in times past, it was thought to be largely of rheumatic character, as the physical signs would hardly account for it; and salicylate of sodium was prescribed, to be given in the dose of ten grains every two hours until relief, with spits, etheris nitrosi f5ss. In the evening the patient was easy while at rest, except on full inspiration, which caused pain at the base of the left chest. The pulse was 129 and the temperature 103° F. Physical examination showed marked bronchial respiration at the base of the left chest behind, but not much dullness on percussion. The following night the patient suffered much from pain and frequent dry cough, and the salicylate was again administered. On the following morning the pulse was irregular, 100. Carbonate of ammonia was given every two hours, and a drachm of brandy once an hour. Salicylate of sodium was omitted.

Was called to patient between 7 and 8 the next morning, and found her in a very alarming condition. The pulse was extremely weak and very intermittent, and there had been several attacks of dimness of sight without actual syncope. Through misapprehension on the part of her attendant little nourishment had been given during the night. She was lying on the right side, the affected lung being uppermost, so that respiration was much impeded. She was immediately turned upon her back, and stimulants were given very freely, with marked relief in the course of half an hour. Ammonia was continued, and stimulants were given through the day, with milk and beef-tea, so that in the evening the pulse was full and regular, and the temperature was 101.6 F.

The next day the patient was in good condition, the pulse in the morning being 111, at 6 p.m. 108. Respiration 30 in the morning, 26 at 6 p.m. Temperature 101° F. in the morning, 101.8° F. at 6 p.m. Bronchial respiration and bronchophony were heard from the left scapula to the base of the lung.

Dr. ABBOT was called at 8 p.m., and found the patient again suffering from violent and irregular action of the heart. There was corresponding irregularity of the pulse, the heart's action stopping sometimes for an interval of six beats. Relief followed in the course of an hour under the free use of stimulants. At midnight he was again called and found her suffering in the same way, but more severely than on either of the previous occasions. Half an ounce of raw brandy was given at once, but caused distress at the epigastrium without any relief to the heart. Half a cup of warm milk was also given, with the same result. As the condition of the patient was very urgent, half a syringe of brandy, diluted with an equal amount of water, was injected subcutaneously in a few minutes, and gave very prompt relief. Within ten minutes the pulse was full, strong, and regular. Since that time there has been no recurrence of heart-failure, the heart-sounds are perfectly normal, and the patient is now convalescent.

The heart-failure in this case was most alarming, and on each occasion seemed to threaten speedy death or thrombosis of the pulmonary artery. There is no disease of the heart, but the patient has been subject to palpitation on moderate exertion. The first attack seemed to have been provoked by the unfavorable position of the patient and the want of sufficient food and stimulants during the previous night. Possibly the debilitating influence of the salicylate of sodium may have had a share in producing it; the attacks recurred, however, after the discontinuance of this remedy. The great value of the subcutaneous injection of stimulants in such an emergency was strikingly illustrated, apparently, in the present instance, saving the patient's life.

Dr. KNIGHT remarked that pneumonia without cough is not uncommon, and spoke of the value of the number of the respirations as giving an indication where to look in cases of concealed pneumonia.

#### NEW YORK ORTHOPÆDIC SOCIETY.

ANNUAL meeting, January 29, 1885. Dr. V. P. GIBNEY, Acting President, in the chair.

Dr. CHARLES F. TAYLOR presented

#### TWO CASES OF TALIPES:

one a hemiplegic equinus in a lad, who presented, in October last, an extreme degree of the deformity. He showed photographs illustrative of the deformity, and stated that he had, contrary to his custom, divided the tendo-Achillis and plantar fascia at one sitting, at the time the case came under his care in October. His reason for doing the operation was that the boy was deaf, and would be hard to "break in" to mechanical treatment. The result has been brought about by the use of apparatus, thus making the case more easy of management. The patient walks

without any apparent deformity of the foot, and the tendo-Achillis is of normal length.

The other was a case of congenital equino-varus, complicated with a spina bifida (dorso-lumbar region), in a girl about six years of age. As shown by photographs, the case was, in September last, at the time of the beginning of treatment, fairly well marked, the degree being about midway between a straight foot and an extreme case of equino-varus. The patient had attended daily at his office. The form of apparatus he now uses will give way soon for another, and the speaker wished to emphasize the fact that he relied on no one form. What was useful at one stage of the treatment was of no service at another stage. Traction by means of adhesive plaster was interfered with by excoriation dependent upon the low vitality of the limb. He now proposes to use a retaining apparatus. The foot had been nearly restored to normal position.

DR. LOUIS HALL SAYRE presented a case of

#### DORSAL CARIES AND SUPPURATIVE DISEASE OF THE HIP.

The deformity of the spine was great, but anchylosis seemed to have been fully established, and the limb was in a good position, permitting an easy gait. All disease was apparently arrested, and the limb could be moved over an arc of about 90°. Three years ago the patient had come under his care, and the spinal deformity was about the same then as now. The disease at the hip had advanced to the second stage, and a large abscess presented. A wire cuirass was used for four months, and the abscess was freely opened, thorough drainage being secured. The hip splint and plaster jacket were employed after the cuirass, and the abscess on the inner side of thigh interfering with the perineal strap, a shoulder was constructed around the lower part of the jacket for the reception of the pelvic band of the hip splint. Counter-extension was thus secured. The child, the speaker stated, had been free from pain during the whole course of treatment, and was now wearing only a plaster-of-Paris corset, the head spring having been discontinued.

DR. A. S. JUDSON read a paper entitled

#### THE MANAGEMENT OF THE ABSCESSSES OF HIP DISEASE.

considering only those cases in which there is deeply seated osteitis. He stated that treatment by the hip splint might, in favorable cases, be expected to prevent abscesses (1) by arresting motion in the joint, thus combating inflammation; (2) by providing an ischiatic crutch, thus protecting the friable bony tissue from injury in walking; and (3) by permitting locomotion, thus promoting the general health. In many cases, however, abscesses are inevitable, whatever treatment be adopted. But, where abscesses occur, if the above treatment of the bone disease is thoroughly practised, they are not a cause of additional anxiety, and do not interrupt the process of repair which is set up by the processes of nature in the diseased bone. A number of cases were cited in which the restoration of the patient, locally and generally, had not been delayed by the presence of collections of fluid or purulent discharges. His clinical experience in cases which

had ended fatally had failed to convince him that the liability to death is increased by the collection and discharge of pus.

He also defended the expectant treatment of abscesses of hip disease, having adopted this view after practising the early and free incision in many cases. He argued that incisions, dressings, the use of drainage-tubes, and the injection of antiseptic fluids deal with the soft parts and the fluids, but are powerless to affect the bony tissue in which the disease is lodged. To use his words: "If the physician chooses to regard himself as a military commander, intent on subduing the enemy intrenched in the bony tissue, let him beware of having his attention distracted by sorties in the soft parts. Let him control the bone disease by fixation, protection, and hygiene, and the abscesses and sinuses will not require the bistoury and drainage-tube."

In support of his views he presented the histories of twelve cases of chronic osteitis of the hip attended by purulent discharges, in which the depurment of the abscesses was described in detail. In a number of these cases the treatment of the abscesses had been purely expectant, and the patients had been restored to perfect health, with useful limbs and a minimum deformity.

#### DISCUSSION ON DR. JUDSON'S PAPER.

DR. STEPHEN SMITH, in opening the discussion, complimented the author in bringing out in such strong relief the old or conservative method of treating cold or congestive abscesses. He believed that all were unanimous in the treatment of hip disease by means of the usual long splint. The older surgeons were governed by two considerations in the management of the consecutive abscesses: (1) They did not believe that such collections of pus were injurious; (2) they dreaded the admission of air into the abscess cavity because of the liability of severe inflammation of the sac or its extension to other tissues. They thus either let the abscess alone, or opened by valvular incision, the object in the latter instance being the avoidance of distention and the admission of air. The aspirator proved to this class of surgeons a valuable aid. When a spontaneous opening occurred, and no inflammation followed, the highest degree of success was obtained. Hence the "let-alone" method. In addition to the pus from the bone, the sac itself furnished a liberal amount, and the drain upon the patient, especially in a child, was often most debilitating, while amyloid degeneration of vital organs was frequently the result. He had seen children recover from hip-joint disease and die of amyloid disease.

The present teaching of surgical science is in striking contrast with this method of treating abscesses. Pus, we are now taught, is an unfavorable complication of any surgical disease. Hence its early removal, together with the cause, follows as a necessity. The methods of procedure are such that the patient need not be disturbed. At a single sitting abscesses that would discharge for months under the let-alone treatment may be obliterated with the cause of the suppuration, and that, too, without subsequent fever or other constitutional changes than rapid convalescence. Even when the pus depends upon carious bone we can remove the dead

portion of bone, cleanse and disinfect the cavity, and secure rapid healing without any constitutional disturbance. The present stage of progress demands this, and he believed it possible, by operation, now to arrest the disease almost in its incipency.

Dr. H. L. TAYLOR commended the paper for the point so well brought out that we no longer treat abscesses, but treat the disease which gives rise to the abscess. He believed, however, that an abscess which gave rise to pressure caused necrosis, and should therefore be evacuated. His experience was based upon the practice of Dr. C. F. Taylor, who, under such circumstances, made a free incision, having found the aspirator ineffectual in removing the floating shreds of necrotic tissue. Moderate pressure after incision was employed, and the results had been good.

Dr. C. F. TAYLOR was in full accord with Dr. Judson on the point that an abscess does not affect the probability of cure. Extensive abscesses, of course, will make a little difference because they mean more extensive disease. Ordinary abscesses, however, that arise during the course of treatment, do not amount to much in the prognosis of the case.

Dr. RIDGON, in confirmation of the views in the paper, cited a case that came under his observation in St. Luke's Hospital in 1878. A large abscess filled the anterior portion of the thigh, and was opened antiseptically, the Lister dressing being applied. To this day, he believed, the abscess was discharging. Another case, in a pale, sickly specimen of a child, with conjunctivitis and purpura hemorrhagica, was also in St. Luke's at this time. The child had hip disease and a large abscess on the anterior surface of the thigh. A spontaneous opening took place, and fully a pint of pus escaped. In three months the patient was discharged cured, and the hip to-day is perfectly well. He had seen a number of cases in St. Luke's where antiseptic precautions were carried out in the incisions, and he had seen many of late years in which spontaneous opening occurred. The latter do better than the former. He waited until the skin became necrotic, then opened, and he believed that in many instances he had killed the patient by departing from this rule and opening early.

Dr. WYETH was so utterly at variance with all the remarks, save those made by Dr. Smith, that he hardly knew where to commence. He could not comprehend why an abscess in or about the hip-joint should receive different treatment than an abscess of the tibia or other part. He did not hesitate to open an abscess wherever he found it. Two of his cases died, he was positive, because he did not open the abscesses, and in this he only followed his teaching. During the last two years he had departed from his teaching. Within the last year he had five or six cases, and in one of these he opened the abscess as soon as he saw it, removing the dead bone by free incision. He found the acetabulum perforated, and removed all the diseased bone, even including the trochanter minor. The child was afterward seized with pneumonia, not connected with the hip disease, and made a good recovery. It is well to-day, so far as the hip-joint is concerned, having been

seen within five months. In another case, similar to this, he had a result equally good, and both were discharged cured in six months.

Just as soon as the suppurating process occurs in an osteitis and arthritis, or a peri-arthritis, and he can find the sign of such an abscess, he believes that the freer the incision and the wider the opening of the wound the better will be the result.

Dr. KETCH stated that the practice of the New York Orthopaedic Dispensary for the past two years had been non-interference with hip abscesses. He was sure that the records would furnish better results during this period than in 1878-79, when it was the practice to open antiseptically.

Dr. H. W. BERG called attention to the views of Billroth, who taught non-interference because, by opening abscesses, the disease was not eradicated, and that one should not interfere with nature unless the suppurating bone were removed. A radical operation, or none at all, is what Dr. Berg insists upon.

Dr. C. F. TAYLOR believed that one may find an abscess depending upon disease in the hip-joint, having, however, no direct communication with the joint, and such an abscess we should treat as an independent condition. These abscesses occur frequently in the later stages of the disease, burrow along the shaft of the bone, and produce superficial caries.

THE CHAIRMAN gathered from Dr. Judson's paper the impression that abscesses arising from *osteitis* of the hip were alone considered, and that the discussion should be so limited. The question then at issue was, Shall the abscess be opened without reference to interference with the carious bone which feeds the abscess, or shall it be left to nature?

The author of the paper regards abscesses as harmless, and the experience of the Chairman coincides with this view, that is, so long as they are not merely opened. If one must interfere, then let a thorough operation be made, whereby all the carious bone will be removed, the cavity cleansed antiseptically, and the limb fixed in the best position possible for recovery. One or two strong objections to the let-alone theory were: (1) the extensive burrowing, sometimes of a collection of pus, thus endangering important tissues by continuity, and leaving a larger extent of tissue for the cicatricial process. This very cicatrization in early life interferes with the development of a limb, and produces unpleasant complication in after life. (2) Amyloid degeneration is a result of prolonged suppuration, especially if the suppuration occur in a child with a tuberculous family history. Dr. Poore has found this true. The views then summarized are: let the abscesses alone unless they encroach upon important parts and occasion much discomfort.

Dr. STEPHEN SMITH remarked that he thought it would be very unfortunate if the first public declaration of this Society was to the effect that pus was a harmless material and may be retained with impunity for any length of time in the tissues of young children; he did not believe that this view belonged to the present era. He did not believe that merely opening an abscess under a spray, and dressing with antiseptic dressings, was all that was required; the treatment must be radical. We have two objects in

view in opening an abscess: (1) Get rid of the pus in order that it may not be absorbed; (2) destroy the source of the pus itself. If the abscess is extra-articular entirely, which may be the case, cleanse it thoroughly, and then close it, employing firm and equitable compression, as with sponges laid over the external surface. Many of these abscesses never suppurate at all. If, however, after this treatment the abscess communicate with dead bone, this must be removed. He had a case recently where he opened the hip-joint, removed the diseased bone, cleansed the cavity, and the case was permanently cured.

The PRESIDENT wished to state distinctly that the Society did not commit itself to *any view*. The freest range in discussion is permitted, and an opportunity will be afforded for the opinion of all.

DR. ROBERTS believed that both laboratory work and modern surgery taught that pus should be removed whenever it is found possible. He detailed the modes of production of abscess in connection with hip-joint disease, and was positive that the treatment employed should depend upon these conditions. He argued that mechanical appliances failing to relieve deep-seated and persistent pain would furnish evidence that the abscess was in the head of the bone. Under these circumstances he would recommend the plan advocated by McNamara of drilling into the head through the trochanter without interfering with the capsular ligament. As illustrating the difficulty of removing by the most thorough operations, he cited a case on which he had operated several months ago, removing portions of head and acetabulum until he fancied he had removed every particle of necrotic tissue. Three or four months afterward he learned that another abscess had formed. General surgery had demonstrated that these abscesses could be cured by proper antiseptic precautions, and the teaching should be heeded.

DR. POORE thought that the tendency of hip disease in patients free from tuberculosis or strumous diathesis was to a cure, while the tendency was the reverse in patients with this diathesis well marked. In cases wherein a tuberculous diathesis was present amyloid degeneration was apt to occur. He had seen cases, too, wherein recovery had taken place despite the amyloid degeneration. He believed that periarticular abscesses in hip disease did connect by an opening, however small, with the joint itself. He, of course, admitted that simply to open an abscess of this kind would not cure the bone disease. Hip disease in children, in his experience, began in an osteitis of the head, or of that portion in close relation with the diaphyso-epiphyseal line. The pelvic bones were also often involved.

It was the speaker's impression that one loses more cases without than with operation. He thought that the same rule that applied to abscesses about the knee-joint should apply to those about the hip-joint. He favored early incision in disease at knee, elbow, and shoulder, and by the same reasoning favored like procedure for a suppurating osteitis at the hip-joint. Illustrative cases were cited, and regret expressed that free incision had not been made. Billroth's rule, he thought, was made for spinal caries. He was perfectly willing to admit that an excised is not as useful as an ankylosed limb.

DR. WILLIAM T. BULL could not speak from any experience in the treatment of hip abscesses, but his results in opening cold abscesses from other sources had been such as to commend this plan. They all closed very promptly. Reasoning by analogy, he believed that the disease could be materially shortened by early interference under strict antiseptics. A case of iliac abscess was reported by the speaker, the sac extending from the upper third of the thigh into the iliac fossa. There was no evidence of bone disease in the history of the case, and after evacuating several pints of pus he could discover no bone by exploration. The sac was fully distended by a solution of carbolic acid, then a drainage-tube inserted, and the whole dressed in the usual way. Healing took place at once.

DR. JENSON, in closing the discussion, called attention to the pathology he had aimed to emphasize, and renewed his statements about treating the bone and the joint, and leaving the abscess to take care of itself. He could see nothing rational in treating the bone by superficial incisions of abscesses. He had nothing to retract.

### Recent Literature.

*The Oleates: An Investigation into their Nature and Action.* By JOHN V. SHOEMAKER, A.M., M.D. Philadelphia: F. A. Davis. 1885.

In this book are set forth the methods of manufacture and the therapeutic effects of the oleates of various alkaloids and metals. The former possess no value, but to the latter class are attributed marked and definite action of various kinds. Our own experience with the oleates has been as yet of too limited nature to permit any well-grounded opinion as to their merits, but so far as it goes, it confirms the opinion of Sigmund that, for the purposes of immunction in the treatment of syphilis, the oleate of mercury is not so efficient or trustworthy as the ordinary mercurial ointment, and also the statement of Living that, in the treatment of tinea trichophytina, the oleate of copper, for which so much has been claimed, is not so good as the oleate of mercury, which is the most commonly used and most useful of the oleates. Of the oleates of iron, silver, aluminium, tin, nickel, etc., we know nothing, and if we did would hardly dare to express any but a favorable opinion, in pavid recognition of the fact that "a very few unfortunate, careless, and injudicious observers, sceptics in therapeutics, who only believe in the older and oft-tried remedies, have taken up the oleates for fashion's or popularity's sake, and after a very limited experience in their application condemn them without a fair trial." G. H. T.

— An esteemed subscriber wishes us to state that a cushion stuffed with curled hair, and made at least three feet square and three inches in thickness, with a hole at the centre six inches across, will be found to be superior to the ordinary india-rubber air-cushion in certain cases where it is necessary to turn the patient over on the side at short intervals for the relief of bedsores.

# Medical and Surgical Journal.

THURSDAY, MAY 28, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by CUPPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM AND COMPANY,

283 WASHINGTON STREET, BOSTON, MASS.

## THE RELATION BETWEEN LUPUS AND TUBERCLE.

FRIEDLÄNDER was the first to express the opinion, published in the sixtieth volume of Virchow's Archives, that lupus is true tuberculosis of the skin. This opinion, based upon the resemblance in structure of the nodule of lupus to tubercle, and the presence therein of giant cells which were regarded by him as characteristic of tubercle, was not generally accepted, it being evident that giant cells were to be found in other processes than tubercle, and also that, as a rule, lupus does not occur in individuals ordinarily recognized as tuberculous. The discovery, however, by Koch, of a special variety of microorganism peculiar to tubercle having furnished a more tangible and evincive method of diagnosis, the detection of the same bacillus in the nodules of lupus crystallized the amorphous opinion of Friedländer into definite fact. The honor of this discovery belongs to Demme, and his results have been confirmed by Pfeiffer, Krause, and Schuchard, Doutelepoint, and others.

The most striking work in this direction has been done by Koch himself, who has isolated the bacillus in question and shown that in its cultivation outside of the human organism its behavior is in all respects the same as that of the bacillus of tuberculosis; and, furthermore, that inoculation of animals with the products of such cultivation has been followed in every instance by the development of ordinary tuberculosis. He also draws particular attention to the fact recognized by all observers that this microorganism is present in lupus in very much smaller quantity than in typical tuberculous products; so much so that only patient search is rewarded by its detection. This fact, which is also true of so-called surgical tuberculosis (*ulc. serofula*), goes to explain the large number of negative results obtained by Cornil and Leloir, who inoculated animals with portions of diseased tissue taken from cases of lupus, and not with the isolated and cultivated bacillus itself.

The identity in the anatomical structure of the nodule of lupus and tubercle taken together, with the

presence in each of apparently the same microorganism, furnishes strong presumptive evidence that lupus is cutaneous tuberculosis, and the only argument brought forward against this supposition by Kaposi and Vidal, who are its opponents, is that the differences in clinical course and appearance between lupus and the rare but typical and well-recognized tuberculous ulceration of the skin are too great to admit of unity of pathogenesis. The obvious reply to this is that the conditions of pathology are too numerous and complicated to permit any such assertion, and that unity of pathogenesis does not of necessity imply unity of result, a notable and common example of which fact is furnished by syphilis.

The assumption that lupus is a form of tuberculosis of the skin is not upset by the arguments which go to show that it has no special connection with hereditary tuberculosis, it being found combined with the latter in only from ten to fifteen per cent. of cases. Human tuberculosis in any situation is usually a localized process, which seems to find in the lungs the most favorable conditions for its propagation and development, and the bacillus of tuberculosis is capable of evolution only under certain conditions of tissue and environment and within a narrow range of temperature. The conditions which obtain in the skin are manifestly hostile to its welfare as compared with those furnished by the lungs, and this accounts for the uncommon occurrence of lupus and its extremely slow advance.

The fact that lupus usually first manifests itself in early life seems to indicate that the skin loses with age its susceptibility to the influence of the bacillus, or, in other words, furnishes less favorable conditions for its development. Such cutaneous susceptibility must be either inherited or acquired, for it is manifestly not common to all individuals.

There is nothing to show that it is hereditary, and everything is against this supposition but the facts that, in a large proportion of cases, lupus is developed only in the neighborhood of cicatrices due to serofulous disease, or upon mucous membranes already altered by catarrhal processes, and that in not a few instances injury or attacks of dermatitis seem to precede the first appearance of the disease, which signify that such peculiarity of skin and mucous membrane is, in part, acquired by reason of antecedent pathological processes. These facts were regarded by Randnitz as going to show that lupus was due to a localized specific predisposition; but, in the light of recent knowledge, they indicate rather an acquired and local predisposition to a special form of infection.

Nor is clinical evidence wanting to show the connection between lupus and tuberculosis, for cases of acute miliary tuberculosis, of "galloping consumption," and of tuberculous meningitis, have been observed, in which the only evident source of infection was preëxisting lupus of the face and extremi-

ties. Such cases are very exceptional, it is true, but under the circumstances they acquire a significance of value out of proportion to their numerical importance, and thereby rendered more conspicuous. What is true of lupus also holds good of many of the manifestations of ordinary scrofula, and not the least boon conferred by our knowledge of the bacillus of tuberculosis is the consequent and final elimination of syphilis as a possible aetiological factor in their production, a possibility which has overshadowed so many pathological problems.

### THE PHYSIOLOGY OF "FALLING BODIES."

THE recent performance of "Professor" Odhum in New York in jumping from the Brooklyn bridge calls attention again to some of the moot points connected with the physiology and physics of "falling bodies." From the nature of the case the physiological questions to a considerable extent can be answered only by *a priori* reasoning. For in fatal cases it must remain undecided what was the proximate cause of death and whether the heart stopped beating before the body struck or not. Our friends, the professors of natorial and saltatorial science, seem disposed however to do what little they can to elucidate these interesting points, and in time some of them may be more fully cleared up.

There seems little reason to doubt that most of the professional jumpers have retained consciousness during their falls through distances ranging up to 130 feet or thereabouts. The man who was killed last week had previously made several high jumps of from 80 to 110 feet without ill effects. In this case the height being 135 feet, the time occupied being about three and a quarter seconds, there was nothing up to the time of his striking the water which would have interfered with perfect consciousness. The rate of motion just before the water was reached was not more than 100 feet per second, a speed not rarely equalled by railway-trains and exceeded by ice-boats. The only way in which this motion could have an effect greater than horizontal motion at an equal rate would be either by involving a sudden change in barometric pressure, or by accumulating the blood in the brain through the *vis inertia*, the motion being in the direction of the long axis of the body. As to the former point, we may say that for the height in question at average temperatures the difference in the barometric record would be hardly more than one eighth of an inch. Of course a change of pressure even to this amount occurring in three seconds is more rapid than one is ordinarily subjected to, but there seems no reason to suppose the body could not accommodate itself to it, even if any effect were produced in so short a time. As to the throwing of the blood back upon the brain by the rapid motion in the direction of the feet, we know that persons who are inexperienced in traveling often sleep in

railway-trains with their feet foremost without evil effects.

It does not, however, follow that because acrobats and sailors can drop 130 feet or so without losing consciousness the same thing would hold true of all persons falling from such a height. The sensation of giddiness caused in inexperienced persons by a high elevation sometimes leads to syncope, and there is no reason why the giddiness induced by high altitude when increased by the terror of actually falling may not cause syncope, if not death by shock, before the concussion comes. We have no right to assume that what may happen to a cool, professional gymnast, taking a leap intentionally, *must* happen in the case of man unused to giddy heights falling accidentally.

The Sam Patches and the Odhums who have met their death from high jumps have done so from the shock of the impact. If they could have struck the water squarely feet foremost they would doubtless not have been killed. We doubt very much, however, in long falls whether, as we find stated by an esteemed contemporary, the individual, be he never so skilful an acrobat, can, unless ballasted, by voluntary efforts maintain a vertical position. As soon as he is withdrawn from his support the centre of gravity of his body tends to assume the lowest position possible. An attempt on the part of the individual to regain his original position, independently of the exceedingly brief time allowed for its execution, will fail because there is no *point d'appui* upon which to work. He can flex or extend his arms and legs upon his trunk by contracting the muscles from their origin, but he cannot, as when in contact with resisting objects, reverse their action and make them work from their insertion upon their origin and so alter the position of the trunk. The fact that a drunken man three years ago jumped from High bridge into the Harlem River, a distance of 115 feet, and was taken up alive, may, perhaps, be interpreted to mean that the immunity enjoyed by the inebriated is a better protection in a high jump than can be gained by a deliberate attempt at maintaining equilibrium.

In falls from a much greater height, such as sometimes occur over glaciers and in the cañons of our western country, though positive evidence must always be wanting as to whether consciousness has been lost before the moment of concussion, there is, we think, a possibility that such is the case. In falling 1,000 feet, for instance, the time occupied being eight seconds, the rate of speed just before the bottom is reached is 257 feet per second, nearly three miles a minute. This would probably induce considerable mental confusion and combined with intense fright probably complete syncope. Supposing the temperature at the summit to be 5° C., and at the base 15° C., the barometric variation would be over an inch. In eight seconds then the individual would experience this change of atmospheric

pressure and also a variation of 10° C. (18° F.) in temperature.

In the fall of a mile, as from a balloon, the velocity just before striking the ground would be 579.5 feet a second, at the rate of some 6.5 miles a minute, and according to the relative conditions of the temperature at the higher and lower point the barometric range would be greater or less but in any event considerable to be experienced in the brief period of eighteen seconds. We would commend a parachute attachment on the head to the consideration of future jumping "Professors," as likely to modify the uncertainties of the trip.

### CHOLERA AND CHOLERA PREVENTION IN SPAIN.

MYSTERIOUS rumors have been coming from Spain for some time back of the active presence of cholera at various points in that country. These were still without official confirmation, when even more mysterious reports find circulation of the successful inoculation against the disease with an attenuated cholera virus, by a Dr. J. Ferrán, of a town called Tortosa.

This follower in the footsteps of Jenner and Pasteur is said to be only thirty-three years of age, and a graduate in medicine of Barcelona. He is reported to have received the honorable notice of the Academy of Medicine of Madrid, some years since, for investigations on microorganisms; and it is also said that he was sent last year to Toulon and Marseilles, during the cholera epidemic. Some months since he forwarded a communication to the French Academy of Medicine, explaining his methods and detailing his results. A committee of the Academy was appointed to consider and report upon this communication.

It is said also that a medical commission will be appointed by the Spanish Government to estimate the value of Dr. Ferrán's method of inoculation.

It is not difficult to believe that cholera is present in Spain, or that the fact of its presence there has been purposely suppressed. It was certainly rather surprising that the country escaped as easily as it did last year. On the other hand, Spain is one of the very last countries from which the past would lead us to expect any light on scientific problems, and especially a discovery so interesting, so important, and so comparatively novel as an attenuated virus of cholera—a discovery which has thus far eluded the most ardent and skilful microscopists of Germany and England. It would seem to indicate a revival of learning and independent thought, for which we confess ourselves entirely unprepared.

Under the circumstances an attitude of judicious scepticism may well be maintained.

### MEDICAL NOTES.

NEW YORK.

—At the autopsy of the man Odium, who eluded the vigilance of the police, and leaped from the Brooklyn bridge into the East River, striking upon his side, it was found that the five lower ribs on the left side were fractured diagonally and that there was rupture of the lungs, liver, spleen, and kidneys. The immediate cause of death is said to have been hemorrhage from the lungs. The height of the jump was 140 feet.

### Obituary.

DR. SAMUEL CABOT.

THE late Dr. Samuel Cabot, who died on April 13th, at the age of sixty-nine years, was a man of decided individuality. He was born in Boston, of Massachusetts stock on both sides. Through his mother, who was a daughter of Col. Thomas H. Perkins, one of the most prominent Boston merchants of his day, he inherited certain marked traits of character.

He was graduated at Harvard College in the class of 1836, and already whilst at Cambridge he developed that keen love for shooting and for the pursuits of a sportsman which he never lost. At the same time his taste for field sports led him naturally into the study of birds and their habits, and all through his after life this interest continued to occupy much of his time and thoughts, and contributed much toward the formation of his character.

Dr. Cabot took his degree of M.D. at the Harvard Medical School in 1839, and further pursued his professional studies in Paris in 1839-40. A journey to Yucatan, with J. L. Stephens, and a long illness, from the effects of which his constitution apparently never recovered entirely, after his return from Paris, brought him late into the profession. During the hours of waiting for professional work he was industriously occupied in preparing and stuffing the birdskins which he had brought home from Yucatan, and in the general work of the Natural History Society, of which he was at that time an active member.

In 1852 he was appointed a Visiting Surgeon at the Massachusetts General Hospital, a position which he held with credit until 1882, when he resigned.

His natural love for children, enhanced by his own domestic life, led him to take an active interest in the Massachusetts Infant Asylum. He had much to do with the establishment of it. In its early days the want of popular sympathy gave it an additional claim upon his support. He never faltered in this work, but stood by it through good and evil report.

Dr. Cabot was one of the early, ardent, and persistent agitators for the abolition of slavery in this country.

His most striking characteristic was a detestation of wrong and injustice, wherever found, and he could not help plunging in with unhesitating sympathy to right it. His temper would sometimes carry him too far, but the impulse came always from the heart. No one was more ready to acknowledge error when he was convinced that he was wrong. Such a mistake never left an angry feeling toward his oppo-

ment. He never harbored a grudge nor did he soon forget his contempt for a mean action.

Absolute honesty of purpose and courage in action, sometimes accompanied, perhaps, with disregard of consequences, made him a power wherever he took an interest. "He hated all pretence, made no professions; but what he believed, he believed, and acted accordingly."

Dr. Cabot married his cousin, Miss Jackson, a daughter of Mr. Patrick Jackson, of Boston, whom he survived several years. He leaves four sons and two daughters. One of his sons follows his profession, and is a member of the Massachusetts Medical Society.

## Correspondence.

### THE TREATMENT OF SCIATICA.

INDIA, ISHITURA, April 6, 1885.

*Mr. Editor.*—After reading of the cures by the newly suggested plan of Dr. Debove for the treatment of sciatica by congelation by chloride of methyl, I desire to make public a process adopted by myself for over fifteen years, as the process is given by no author that I know of, but was hit upon by myself after persevering attempts to deal with such cases, and I have found the method very successful.

I make issues with small pieces of solid caustic potash, so regulating the size that the slough will never exceed the size of a threepenny, or at most a sixpenny, piece. Such application gives a sharp gnawing or burning pain for about fifteen minutes, when it stops. The pain is not as great nor as continuous as that of actual cautery. The pain of the sciatica generally leaves after the effect of the application, or if the complaint is of very long standing invariably leaves by the time the scab comes off, which takes about a week or a fortnight, and sometimes has to be encouraged to separate by poultices.

This treatment was adopted by me as a last resort, when all the processes suggested as cures for sciatica had failed, even the application of actual cautery.

I explain its action as follows: The cautery by caustic potash takes a deeper effect than other cauteries on the skin and tissues underneath, stirs up by the inflammation it excites a deeper revulsive effect, which is necessary, as the sciatic nerve is deeply seated at its exit from the ischiatic foramen. The cause of the pain in sciatica, when not from actual pressure on the nerve, I ascribe to some irritation, as of syphilitic poison in the system or to a subacute inflammation of the neurilemma. A further stage is effusion into the nerve sheath from which results the insensibility of the part which the nerve supplies, and such effusions the caustic potash has removed, and with them the insensibility which they cause. These issues have also been of service in my hands in the treatment of anesthetic leprosy.

Very respectfully yours,

J. O. PIERCE, M.R.C.S. Eng.

### COCAINE WITH Pilocarpine.

Boston, May 19, 1885.

*Mr. Editor.*—In connection with the newly awakened interest in the drug cocaine, it is worthy of note that its combination with pilocarpine removes the only drawback to its use in operating upon the eye, that is, the dilatation of the pupil and paralysis of accommodation.

A mixture of ten drops of four per cent. solution hydrochlorate of pilocarpine in a drachm of four per cent. solution hydrochlorate of cocaine secures the anesthetic effect of the cocaine, leaving the pupil and

accommodation absolutely unaffected, as I have been able to demonstrate a sufficient number of times to assure myself that the neutralizing effect of the pilocarpine is constant and innocuous. Yours truly,

H. W. BRADFORD, M.D.

### PARIS LETTER.—MEDICAL MATTERS IN PARIS.

[FROM OUR SPECIAL CORRESPONDENT.]

PARIS, May 9, 1885.

*Mr. Editor.*—It is not the fashion to-day among Americans to go to Paris for medical instruction. In coming abroad for that purpose our men, whether they have just won their diplomas or have been years in practice, usually go straight to Germany, and after having concluded their allotted period in that country, or in Vienna, they take a look at the French and English schools. There is good reason for this. The German schools in many respects are in advance and they teach anatomy, diagnosis, pathology (which, perhaps, is the strongest attraction to foreigners), histology, and the specialties perfectly. Material is plenty, and teachers excellent. Probably no American physician is ever satisfied with German or French therapeutics. American travelers of experience, in case of need, choose an American physician if they can find him, an English doctor if not, having already discovered that the methods of the Germans and French are neither those to which they have been accustomed, nor do these methods so quickly relieve their symptoms. In American therapeutics there is a simplicity, a directness, and an insight which seem to be lacking in European modes of treatment. To discover reasons for this indisputable fact is unnecessary here, but parenthetically the matter is worthy of mention. A physician who means to practise in America should study his therapeutics in that country, but everything else which pertains to medicine, surgery, and obstetrics he may study abroad with benefit. In doing this he should not neglect Paris. Nevertheless he will find matters to criticize. Indeed, it is frequently of great use to study a wrong, in order to be clearer as to the right method. The old faults of lack of cleanliness of wards, patients, and bedding, lack of ventilation, lack of hygienic conditions, which we should consider a *sine qua non* of success, are painfully evident in certain of the hospitals of Paris. This is said not to be the fault of the medical men who serve these hospitals, but that of the lay boards of administration, to whom the physicians and surgeons apply in vain for relief. It is a surprise to be told that this neglect of the administration arises from their absorption in politics.

The newer hospitals are freed from this objection, though it is difficult to see why a hospital centuries old cannot be kept sweet and clean. The medical teachers in Paris are almost without exception thoroughly capable of instructing their classes. They are ready, fluent, fertile in illustration, and very clear in statement. About French surgery still clings the glamour of its old renown, and French surgeons have lost none of the grace, boldness, and skill which have always been characteristic of them. They are devoted to Listerism and the antiseptic dressing, but there is a great difference in the outcome of their after-treatment. The percentage of erysipelas in their cases differs widely in different hospitals. Pédalion, after five years' observation in *La Pitié*, finds that there are as many cases of erysipelas as before the introduction of the antiseptic treatment, but that the cases are less virulent, while other surgeons have reduced their percentage to a very low figure. This has given rise to a discussion in the *Revue de Médecine*, in the course of which Verneuil (*La Pitié*) complained of the frequency of erysipelas, and French medical journals speak of the results published by Pédalion as astonishing, remarking that Le Fort (*Hôpital Necker*)

confesses to only a few cases, and that Guérin, since the introduction of the aseptic dressing of cotton wadding, has seen none at all. Trélat (*Hôpital de la Charité*) in this discussion consequently affirmed that surgeons did not follow the same manner of using the antiseptic procedures, some having open dressings and frequently wash suppurating wounds; others using closed dressings, washing rarely, and adopting the other method only when forced. The former, according to Trélat, voluntarily expose their wounds to perilous contacts. To-day, in grave operations, a dressing is made at the end of twenty-four hours, a second eight days later, and at the third the patient is well. To renew the dressings as rarely as possible is Trélat's formula. This would mean that many surgeons apply their dressings negligently.

*L'Union Médicale* thinks that some of the old hospitals are infected and that in these antiseptic defence is difficult, and instances wounds of the mouth, anus, and rectum which it is not easy to dress aseptically. "Nevertheless," it adds, "it is doubtless true that the surgeon who has the least erysipelas is he who most thoroughly protects his wounds." Requier read a paper to the effect that in Philippsville, Algeria, erysipelas, in the mean, since 1874 has been reduced in military wards from 11 per cent. to 3.6 per cent.; in civilian wards from 8.9 per cent. to 2.2 per cent. At Batna results differ. There, within the same period, the percentage has risen from nine to ten in military wards; from six to seven in civilian wards. His explanation was that in Batna the men, fatigued by sojourn and labor in heated Southern districts, present to the germs of erysipelas a culture-surface favorably prepared. It is not easy to say why, during the discussion, no surgeon alluded to the mal-hygienic conditions of some of the old hospitals of Paris as a reason for increase or continuance of erysipelas in spite of antiseptic treatment. It is not worth while to give details, but some of these hospitals would startle and amaze one who was accustomed only to the sweetness, airiness, and cleanliness of our hospitals, of their patients, the bedding, etc.

The spray is largely used in certain quarters. Even in some medical wards the atmosphere is kept saturated with carbolic acid, and in the corresponding surgical wards whenever a wound is opened the atomizer, following the surgeon upon the ward wagon, keeps the spray flying upon the patient, to the great annoyance of students who wish to examine. This shows, however, that antisepticism is not neglected. In these cases the wounds were sopped with cotton wadding dipped in a solution of phenic acid and syringed with a solution of boracic acid, by means of the Potain bottle in connection with an air-bulb of rubber. The temperature of the latter solution was invariably many degrees below that which we should use. In a case of empyema, which had been treated by the radical operation, the chest was washed out with boracic fluid far below the temperature of the blood and the wound was sopped in the manner indicated. The dressing was reapplied very carelessly.

I saw a very neat and careful dressing applied by Trélat after the removal of a tumor above the eye. Next the wound iodoforimized pledgets of gauze covered by a dry compress, a bandage of cotton wadding, another over this of gauze, and finally a roller bandage of thin rubber tissue, all having been made antiseptic. The entire head was enveloped and the dressing very handsome. In his operations Trélat uses bits of carbolized cotton-wool, previously dried, often rather than sponges, the pledgets being brought in closed jars. Trélat is a very steady, quick, and neat operator, and an unusually excellent lecturer, sharp, clear, and dramatic. He takes his students through the wards on a surgical visit, afterward adjourning to the lecture and operating room (a small, dingy amphitheatre with far too little space, in which he asserts he

dares not do certain operations for fear of contagion), and here he describes the cases upon which he is to operate, gives carefully the diagnosis by exclusion, the pathology, the macroscopic and probable microscopic appearance of tumors, if any, and then does the operations in the order of the schedule. The anamnesis of each case is read from the records. This is the plan followed in most of the Paris hospitals. Medical visitors should not fail to see Trélat at *La Charité*.

In the opening lecture of the summer course he bitterly inveighed against the manner in which the hospitals of the French capital are conducted, and compared them unfavorably in this respect with hospitals of England and Germany. In Paris it seems that "the service," that is, the surgeon and his assistants, of whom Trélat has at least a round dozen, are fettered by the outside daily engagements (microscopic, laboratory, pathological, anatomical, etc.) of the various staffs; so that he confesses himself not only unable to follow with the proper care any special line of treatment, but likewise embarrassed by the exposure of the members of his staff, in their daily callings, to atmospheres which endanger the success of his operations. Moreover, in a most amusingly scornful manner, he satirically alluded to the "insupportable" lack of cleanliness about him, though he had far, far less cause than the surgeons of other hospitals. In Paris there are twenty-four surgical services similar to his own and the same difficulty holds good with all of them. But the administrators of hospitals evidently do not give their surgeons the power which properly belongs to them. Even the hygienic condition of the hospitals is rather at the negligent mercy of the administrative boards than under control of the surgeons and physicians. In England and Germany the continuous service of *internes* of years in duration gives the surgeon a greater dependence upon his assistants, as well as greater certainty of success in operation, than if the staff were interested in outside matters and changed their service as soon as they became accustomed to their chief and he to them. The latter difficulty is another cause of Trélat's complaint.

Péan, at the *Hôpital St. Louis*, has the name of being the most graceful surgeon of Paris. At *Hôtel Dieu*, Richet, picturesque, calm, and courageous in operation, is a very attractive old man, a most excellent expounder of the principles of surgery, and draws together a goodly number of students, who, of course, may choose their own man. Verneuil, at *La Pitié*, has a grace, *bonhomie*, and *verve* which recall the elder Pancoast, but his hospital is against him. It is very old and unsavory. Of the medical clinicians Jaccoud, Potain, and Sée are easily first. Jaccoud's published lectures are voted, by the students, heavy, extended, and pedantic, but as a lecturer and diagnostician he is highly prized and is a valuable member of the Faculty. His prompt, soldierly manner is carried into his diagnosis, which is very decided, distinct, and clear. It is a satisfaction to examine a patient after Jaccoud has delineated the symptoms. He is at *La Pitié*, where, unfortunately, he labors against a complete lack of ventilation. At *Hôtel Dieu*, with its imposing quadrangle of granite and six hundred beds, one finds modern methods of keeping air, floors, *latrines*, and apartments cleanly. Here Sée, of course, attracts a large class and his word is law. Potain, at *Hôpital Necker*, has a tiny lecture-room, which is well occupied after the morning visit. He is a small, quiet-looking man, lectures in a monotone, but is full of suggestion, and makes one feel that he thoroughly comprehends the presentation of his cases. At *La Salpêtrière* (a town in itself of upward of four thousand souls) Charcot is the attraction, and his specialty—nervous diseases—being the notable cult of the day, he is never forgotten by the medical visitor. Fournier, at the *St. Louis*, has a good clinic for syphilitic and skin diseases.

In giving their clinical lectures after the ward visit, the chiefs of the clinic are invariably accompanied by their assistants and are fenced off from the audience. The chief always wears his long white apron (and white jacket besides, if a surgeon) and black skull-cap of silk or velvet, as do several of the assistants, all of whom take careful notes of the lectures. The caps are never removed. These occasions are very interesting. The utmost quiet and closest attention are the rule.

Laboratory work of every description is well developed in Paris, and although our great respect for

German thoroughness and culture in histology, normal and pathological, in chemical analysis, and other laboratory science leads us to gravitate to that country for study, the present condition of scientific work in Paris renders that city worthy of comparison with German University towns. Indeed, one meets students from our side of the sea who have followed the medical courses in Paris three or four years. Undoubtedly a previous familiarity with the German or French language influences men in their choice of schools.

[To be continued.]

H. O.

# REPORTED MORTALITY FOR THE WEEK ENDING MAY 16, 1885.

Deaths reported 2,297; under five years of age 815; principal infectious diseases (smallpox, measles, diphtheria and croup, whooping-cough, fevers, and diarrhoeal diseases) 328, lung diseases 375, consumption 337, diphtheria and croup 105, diarrhoeal diseases 67, measles 13, scarlet fever 11, cerebro-spinal meningitis 10, typhoid fever 15, malarial fevers 16, whooping-cough 14, erysipelas 11, puerperal fever three, smallpox two. From scarlet fever, New York 16, Boston seven, Philadelphia five, Baltimore, New Orleans, and New Bedford two each, Brooklyn, Lynn, Springfield, Holyoke, Salem, Gloucester, and Haverhill one each. From cerebro-spinal meningitis, New York seven, Nashville and Fall River two each. From typhoid fever, Philadelphia seven, New York, Brooklyn, and Boston two each, Baltimore, District of Columbia, Providence, and Cambridge one each. From malarial fevers, New York and New Orleans six each, Philadelphia, Brooklyn, Baltimore, and Charleston one each. From whooping-cough, New York and Philadelphia four each, Brooklyn three, Boston, Baltimore, and District of Columbia, one each. From erysipelas, Philadelphia three, New York, Boston, and District of Columbia one each. From puerperal fever, Philadelphia, Boston, and District of Columbia one each. From smallpox, Philadelphia and Boston one each.

Cases reported in Boston: measles 63, scarlet fever 38, diphtheria 21, typhoid fever five.

In 108 cities and towns of Massachusetts, with an estimated population of 1,317,931 (estimated population of the State 1,555,101), the total death-rate for the week was 17.52, against 17.93 and 19.73 for the two preceding weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,906,116, for the week ending May 2d, the death-rate was 24.1. Deaths reported 3,601; infants under one year of age 878; acute diseases of the respiratory organs (London) 337, measles 176, whooping-cough 127, diarrhoea 30, scarlet fever 33, diphtheria 25, fever 22, smallpox (London) 32, Manchester two, Liverpool, and Halifax one each) 26. The death-rates ranged from 15.4 in Derby to 31.1 in Newcastle-on-Tyne; Birkenhead 20.2; Birmingham 21.8; Bradford 23.1; Leeds 23.0; Leicester 20.3; Liverpool 21.3; London 19.8; Manchester 30.6; Nottingham 15.5; Sheffield 22.0; Sunderland 23.7. In Edinburgh 19.1; Glasgow 27.6; Dublin 33.5.

For the week ending May 2d in the Swiss towns there were 36 deaths from consumption, lung diseases 29, diarrhoeal diseases 13, diphtheria and croup 10, smallpox four, scarlet fever three, and puerperal fever each three, erysipelas and measles each two, whooping-cough and typhoid fever each one.

The death-rates were: at Geneva 9.1; Zurich 21.2; Basle 21.2; Berne 31.7.

The meteorological record for the week ending May 16th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

# OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MED- ICAL DEPARTMENT, U. S. ARMY, FROM MAY 16, 1885, TO MAY 22, 1885.

VOLLME, EDWARD P., lieutenant-colonel and surgeon. Granted leave of absence for three months, to take effect when his services can be spared by his department commander. S. O. 110, A. G. O., May 14, 1885.

DELOFFRE, A. A., captain and assistant surgeon. Relieved from duty at Fort Snelling, D. T., and ordered to Fort Totten, D. T., S. O. 52, Department of Dakota, May 14, 1885.

MUNDAY, BENJAMIN, first lieutenant and assistant surgeon. Relieved from duty at Fort Klappan, Oregon, and ordered to Fort Walla Walla, W. T., S. O. 72, Department of Columbia, May 12, 1885.

## SOCIETY NOTICES.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — A regular meeting of the Society will be held at the Medical Library, 19 Boylston Place, on Monday, June 1st, at 8 P. M. Readers: Dr. E. Cowles, "Insanity of Doubting, or of Fixed Ideas, and its Frequency." Dr. J. H. Denny, "Toxic Paralysis and the Industrial Use of Poisons." H. L. BIRRELL, *Secretary*.

SEATTLE DISTRICT MEDICAL SOCIETY. — The *Section for Clinical Medicine, Pathology, and Hygiene* will meet in the hall of the Harvard Medical School, on Tuesday, June 9th, at 8 o'clock. Papers: Dr. W. N. Ballard, of Boston, "A Case of Progressive Muscular Atrophy," with presentation of the patient. Dr. W. Everett Smith, of Framingham, "Hereditary Ataxia, with six new cases." Microscopic Demonstration of Spinal Cord and exhibition of patient. Dr. E. C. Seaman, of New York, Drs. S. G. Webster, G. F. Jelly, J. J. Putnam, C. P. Folsom, J. H. Denny, H. P. Quincy, and others are expected to take part in the discussions. Members of the profession are cordially invited to attend.

ALBERT N. BLOMGETT, *Secretary*.

## OBITUARIES.

Dr. J. W. D. OSGOOD. — Dr. Jonathan Walter Dandolo Osgood died at Greenfield, Mass., May 15th, aged eighty-two years and ten months. He was born in Gardner, Mass., where his father was both preacher and physician. He was a graduate of Dartmouth College in the class of 1823. He studied medicine at the University of Pennsylvania and at Dartmouth, receiving the degree of M.D. at the latter place in 1826. He first practised in Templeton, moving to Greenfield in 1828, where he had an extensive and lucrative practice. The autopsy showed ossification of the coronary arteries. Dr. Osgood was Vice-president of the Massachusetts Medical Society in 1876.

PROFESSOR HEINLE. — Dr. Frederic Gustave Jacob Heine, one of the most distinguished workers in the field of anatomical science, has just died at a ripe age. He was born at Erfurt, Saxony, July 9, 1809. Having had the advantage of a good education, he subsequently began the study of medicine. He entered upon his studies at Heidelberg and completed them at Bonn. At the latter place he received his degree of Doctor in 1832, and from there went to Berlin, where he became an assistant in the anatomical museum. Two years later he was appointed professor to the medical faculty of the university, but soon after

fell into disfavor on account of having affiliated with the secret societies of the students called the "Burschenschaften." For this he was cast into prison, and, although he received a full pardon and was released soon after his incarceration, he was unable to again establish himself in favor in the university until 1837, when he returned as a private tutor. During the three succeeding years he gave instructions in pathology and in microscopic anatomy, then an unexplored field. During this period he was a contributor to the *Annual Reports* of Caustat, and published "Ueber Schlimm und Fieberbildung," which was first brought out at Berlin in 1838. The following year he published at Leipzig "Vergleichende Anatomie des Kehlkopfs," a work descriptive of the development of the larynx in animals, from man down to the very lowest types of creation. In 1840 he became professor of anatomy, and later of physiology, in the University of Zurich. The same year he produced another valuable work, "Pathologische Untersuchungen," published at Berlin. This work was a series of observations on the nervous system, the periodical nature of certain maladies, and many other nervous affections. In 1844 he was called to the professorship chair at Heidelberg, having the departments of anatomy, physiology, pathology, and anthropology, and this position he held eight consecutive years. It was during this period that his most important work, "Handbuch der Rationellen Pathologie," appeared, which was the crowning effort of his life. In 1852 he became professor of anatomy and director of the Anatomical Institute at Göttingen. It was here that he opened a new field to science by the adaptation of the achromatic microscope for anatomical purposes. Among others of his many important works are "Handbuch der allgemeinen Anatomie," given to the public in 1841 at Berlin, and "Handbuch der systematischen Anatomie des Menschen," which was published at Brunswick in 1855. The second volume of this last work was issued in 1864, and was followed by the third and last four years later.

PROFESSOR PANUM. — Professor Panum, the incumbent of the chair of Physiology at Copenhagen, and perhaps better known as the President of the last International Medical Congress, has recently died. Professor Panum has for many years been known as one of the ablest workers in the field of medical and physiological science. His observations have been made largely in the field of scientific pathology, and he has left behind him a mark in one of the most difficult fields of medical research. Panum exhaustively treated the subject of transudation by physiological experiment, making also an elaborate series of experiments on artificial embolism of the various vessels of the body. He showed that fibrin is not necessary for resuscitation by transudation, and that even with the greatest care it may act injuriously by clotting. His work on "Embolism" ranks with the classical writings of Virchow and C. Weber. His observations on the nature of the virus of septicaemia, made many years ago, convinced him that it was independent of the agency of living organisms. His address on "Food Rations for Man in States of Health and Disease," delivered at the International Medical Congress last year, contains valuable suggestions on the physiology of diet. Of late years he experimented largely on the formation of "physiological fistula" in the small intestine, with a view of studying the nature and properties of the intestinal juice unconfaminated with other secretions.

## DEATH.

Dr. J. W. D. OSGOOD. — In Greenfield, Mass., May 16, 1885, Jonathan Walter Dandolo Osgood, M.D., M.M.S.S., aged eighty-three years.

## DOUBLE CONGENITAL DISPLACEMENT OF THE HIP; DESCRIPTION OF A CASE WITH TREATMENT RESULTING IN CURE.

(With Plates.)

BY BUCKMINSTER BROWN, M.D.,

Consulting Surgeon of the House of the Good Samaritan, &amp;c.

WHEN in Paris during the winter of 1845 and 1846 I was much interested in observing, among the cases in the wards of M. Guérin at the Hôpital des Enfants Malades, three or four of congenital dislocation or displacement of the hip. I was not able to follow them a sufficient length of time to learn the degree of success attending the treatment. M. Guérin was sanguine that the result would be favorable.

In 1843 "l'ancien conseil général des hôpitaux et hospices civils de Paris" appointed a commission to follow, for a time not less than one year, the treatment pursued by M. le docteur Jules Guérin in the Children's Hospital of Paris in cases classed under the head of Orthopedic Surgery. The commission was instructed to report upon the cases so followed and examined. It was composed of MM. Rayer, Serres, Louis, Breschet, Jobert, and Blandin. The council also appointed M. Orfila as president.

In 1848 the report of this committee was published.<sup>1</sup> The fourth class of cases reported upon was congenital luxations of the femur. Of this description of cases there were five submitted to the commission for observation and examination. Of these five, four were examples of single, and one of double, dislocation. The first two patients presented were girls, one six and the other seven years of age. In each, one joint only was affected. These cases were under the notice of the reporters from December 3, 1843, to December 28, 1845. The result was not a permanent replacement of the head of the femur in either of the cases. But, much to the surprise of the committee, there was found in each case an elongation of the long bones of the leg to the extent of two centimeters. In this way compensation was established for the shortening produced by the luxation.

Such was the result of the examination of the committee and testified to in their report.

Upon the point above referred to I will quote a personal observation made about the same period that this committee was pursuing its investigations:—

"There is yet another class of cases. In certain children the resistance to the means employed for producing a descent of the head of the femur is so great as to render these efforts wholly ineffectual. What is very curious in these cases is that there is an elongation of the bone itself. Thus we have still the signs of dislocation on examining the hip-joint, but on comparing the two limbs we find them of the same length."<sup>2</sup>

The third case reported upon, after fourteen

months' treatment promised success. Most unfortunately, however, the patient had typhoid fever attended by severe cerebral symptoms, and by general convulsions and contraction of the muscles of the trunk and limbs. The displacement returned worse than it was originally. After extension, the trochanter was again brought into position, and hopes were entertained of a cure. Without known cause the luxation returned, and at the date of the report the case was still under treatment. Of the two other cases one was not treated, on account of the occurrence of some other malady.

The fifth subject, being the double displacement, was under treatment at the time of the report.

Thus we have five cases of this malformation presented by M. Guérin to an especially appointed commission. In two of these, as I have stated, the treatment was terminated at the end of two years. In neither of them was the malposition remedied. The third and fifth were still under treatment, and in the fourth, as before mentioned, no attempt was made at restoration.

Contributions have been made from English, French, and Italian writers to elucidate the pathology and aetiology of this class of cases.

Dr. Carnochan, of New York, has written a valuable monograph upon this subject, in which he describes and exemplifies, with plates, the anatomical relations of the displaced bones and the changes which occur in the pelvis after a lapse of years. He likewise gives plates, copied from a report of M. Pravaz, representing apparatus for extension and for exercising the joint, which, judging from the diagrams, must be extremely complicated, unwieldy, and expensive. These, however, Dr. Carnochan has not put into any practical use so far as can be gathered from his work. No case illustrative of treatment and cure is related by him.

Brodhurst has had a number of these cases under his care. He advises in all cases, except in children under two years of age, the division of "all the muscles" which are inserted into and about the trochanters, especially the glutei and the rotators.

This author relates a case of single displacement in which he did this operation, and the patient, with the assistance of a thickened sole, walked well. Similar operations were performed by M. Guérin in the cases to which I have previously referred.

Dr. Sayre recommends his instrument for extension of the hip during locomotion and also Darrah's wheel-crutch.

"M. Pravaz, Jr., has put on record the case of a girl, aged seven years and a half, in which he claims complete success in the reduction of a dislocation of this nature by a prolonged treatment."<sup>3</sup>

In this instance there was unquestionably a well-defined acetabulum, as, when the head was reduced, it went in with a "distinct snap." In this respect the case of M. Pravaz essentially differs from the one hereafter to be described in this paper. So important a fact as the existence of a pronounced socket places the parts to be acted upon in an entirely dissimilar condition. Dr. Carnochan likewise alludes to the report upon this case of M. Pravaz.

<sup>1</sup>Rapport Adressé à Monsieur le Délégué du Gouvernement Provisoire sur les Traitements Orthopédiques de M. le docteur Jules Guérin à l'Hôpital des Enfants Pendant les Années 1843, 1844, et 1845, par une commission composée de MM. Blandin, P. Dubois, Jobert, Louis, Rayer, et Serres; Président, M. Orfila. Paris, 1848.

<sup>3</sup>The Surgical Treatment of the Diseases of Infancy and Childhood, p. 235. T. Holmes.

Mr. H. A. Reeves, of London, in a work just published (1885) says: "My opinion is that in a large majority of cases anything other than palliative measures, such as the use of appropriate apparatus for grasping the trochanters and keeping them as far as possible in place, is of little use. Pravaz claimed to have made cures by the use of his special apparatus, but Bouvier and others have fairly shown that these were not permanent cures."<sup>4</sup>

Dr. James Knight, in his recent work on Orthopaedia, relates a case where "after two years' treatment the patient was enabled to walk independently of support to body or limbs." Further particulars are not given; as whether after treatment the position of the femoral head was normal or otherwise, or if there was a cotyloid cavity before or after treatment. So far as my knowledge extends these cases are usually able to walk.

Dupuytren wrote a memoir on this subject and expressed his opinion that there was no remedy, and not even a palliative for these displacements.<sup>5</sup>

Mr. Thomas Bryant, in his standard work on Surgery, in writing on the treatment of cases of this malformation, says: "Nothing can be recommended with the view of cure, for art cannot supply a natural deficiency or make up for a defect of structure in the bones of the joint. . . . Mechanical appliances are to be condemned as useless, if not worse. They have been employed on a wrong principle, or rather on a want of due appreciation of the conditions of parts, and therefore with only a vague hope that they may do good. These observations apply as much to the use of an extension apparatus as to operative interference, although with more force to the latter."<sup>6</sup>

Coxectomy has been performed for relief in this affection.

I quote from the *Medical News* for October, 1884: "Congenital dislocations of the head of the femur, especially when they have existed for some time, are notoriously unamenable to permanent relief, the means resorted to for this purpose being as a rule directed to limiting the tendency of the bone to further displacement by wearing a strap of webbing around the hips.

"At the recent *Versammlung der Deutscher Naturforscher und Aerzte*, in Magdeburg, Dr. Heusner, of Burmen, demonstrated that such cases are open to more radical measures, and placed on record the first excision of the hip for congenital dislocation. The operation was done for excessive suffering in the left joint of a girl twenty years of age. The ligamentum teres was absent, the head of the femur was about as large as that of a child of six years, ovoidal in shape, and much flattened, and its surface was uneven and the neck of the bone formed an obtuse angle with the shaft. The acetabulum was fully developed and of normal size, although its rim was somewhat flattened and polished above and below.

"The head, neck, and nearly an inch of the shaft of the femur having been excised, the acetabulum

was made deeper with the chisel and the parts brought into apposition. At the expiration of eleven weeks, with the aid of a cane the patient was able to walk without fatigue for half an hour, the pain was relieved, and there was every prospect of future good use of the limb.

"The case briefly narrated shows that the theoretical objection to operative interference in congenital dislocations of the hip, based upon the absence of a well-formed cotyloid cavity, is not well founded. Even if the acetabulum were superficial or deficient a cavity of sufficient size to accommodate the divided shaft of the femur could be chiseled out of the ilium." Operations similar to the one above described have been performed by Margary, of Turin, E. Rose, and C. Reyher.

The behavior of the hip-joint in other circumstances, as in traumatic unreduced dislocations, etc., would unquestionably lead to the belief that a cure could be effected by following the teachings, and taking advantage of the hints thus obtained, and by the combination of physiological and mechanical means, without having recourse to the heroic measures above described. My confidence, however, in the success of treatment has been so slight, and the circumstances of the patients who have presented themselves have been such, as not to warrant me in testing a course of procedure tedious and wearing at the best, whether operative or mechanical, and of which the history of cases, where any minute record has been given, has not been for the most part encouraging.

Connate malposition of the head of the thigh-bone is comparatively a rare affection and occurs most frequently double. Dupuytren says: "Simultaneous displacement of both femurs is observed in most individuals affected." Carnochan also states, as the result of his researches, that dislocations on both sides are the most frequent.

The prominent symptoms in those cases where both hips are displaced are, first, the peculiar waddling walk, and second, the extreme spinal incurvation.

The swaying walk is due mainly to the extent of surface traversed by the heads of the femurs. The acetabula being absent or deficient, the capsular and round ligaments, if present,<sup>7</sup> are so stretched as to have no influence in limiting the motion of the femoral heads, which are held alone by the muscles and fascia.

Thus, in raising the foot in walking, the weight of the limb extends the muscles connected with the neck of the femur and trochanter, and the head of the thigh-bone sinks one or more inches. In placing the foot upon the floor the weight of the body causes it (the head) to slide upward again as far as the insertion of the muscles will permit. In this way a smooth sac is formed either by the capsular ligament, or if this has been ruptured, as sometimes occurs, immediately beneath the muscles on the external surface of the ilium. This is probably bursal-lined, and from the difficulty of producing adhesion between its sides is an additional impediment to permanent restoration.

<sup>4</sup> *Bodily Deformities and their Treatment*, p. 308. By Henry Albert Reeves, F.R.C.S.E. Philadelphia: F. Bickleton, Son & Co. 1885.

<sup>5</sup> *Mémoire sur le déplacement originaire ou congénital de la tête du fémur*.

<sup>6</sup> *A Manual for the Practitioner of Surgery*, p. 769. By Thomas Bryant, F.R.C.S. Second American Edition.

<sup>7</sup> According to a traveller, this latter ligament is often undeveloped and sometimes wanting. *The Mechanism of Dislocation and Fracture of the Hips*, p. 21. By Henry J. Bigelow, M.D. It may be that in some cases of congenital displacement of the hip such a state of things exists.

The lordosis is simply the natural attempt to gain an equilibrium. The upper part of the body being thrown from the median line by the displacement backward and upward of the femoral heads, a counterpoise is necessitated where only it can take place, and an unavoidable anterior lumbar curve is the result.

The following records of an interesting and rare case are written in the hope of their being of service to members of the profession, who, in undertaking a similar case, may be glad to have the narration of such an experience to turn to, to aid them in their labors. With this in view the apparatus, which was found fully to answer its purpose, has been accurately photographed and described, and every important step toward restoration carefully noted. The apparatus used was designed as the objects to be accomplished and the exigencies of the treatment presented themselves.

On the fourth of April, 1882, a little girl four years of age was brought to me to be treated for what was thought to be an unusual example of spinal curvature. On examination, I found a double hip displacement.

As on former similar occasions and for reasons already mentioned, I decided against active treatment. The state of the case was clearly placed before the parents, accompanied by the statement that an attempt at restoration would involve a course of treatment not unattended with risk, at least in some of its phases, necessarily prolonged, and so extremely uncertain in its results that I did not feel justified in advising its adoption.

The parents of this child, however, were not to be dissuaded from making an attempt to relieve their daughter from so distressing a condition.

The thought of its continuance with its blighting influence through life was unbearable. After weeks for mature deliberation they decided that the trial should be made, if I were willing to undertake the treatment. The condition of the hips at this time was as follows: No trace of a cotyloid cavity could be discovered. When the patient was recumbent, if the shoulders were firmly held by an assistant, traction on the legs would readily bring the heads of the femurs into their normal position, and they could as easily be pushed back again, or they would slip upward by the natural contraction of the muscles. There was no spasmodic or spastic contraction. The muscles acted powerfully, but not abnormally. There was no such action of a muscle or group of muscles as would demand or warrant the use of the knife. I have said there was strong muscular action, and after prolonged extension, if the hand was laid upon the nates or pelvis, it was curious to feel the fibrous, fascicular, wormlike movement by which the limb was slowly drawn upward over the ilium. This was the simple, natural, muscular contractility brought into play after resistance had been removed. The head glided upward over a smooth surface. The walk was the extreme of that sideward movement which is expressed by the term waddle. It was a much exaggerated waddle. Plate 1 represents the displacement viewed laterally. The great trochanter is seen as a rounded prominence high up on the ilium, bordering on the crest. The muscles are stretched

and bagged up by the pressure of the weight of the body on their tissues. The excessive lordosis is conspicuous, showing the obtuse angle at the junction of the lumbar vertebrae and sacrum.

The consequent prominent, overhanging abdomen and compensatory bend of the knees are well seen in this side view. Likewise the shortening of the stature is evident. Plate 2 represents the appearance of the child seen anteriorly. It depicts the height of the trochanters on a level with the upper rims of the ilia, and the projection in front. The splayfoot, or valgoid tendency, the usual accompaniment of this condition, is also well marked.<sup>2</sup>

The child was brought to Boston, and on the thirtieth day of December, 1882, she was placed upon the bed. I will here premise that for many of the dates and for much of the minute history of the case I am indebted to a diary kept by the mother of the patient.

Obviously my treatment must be divided into distinct stages. First, it was requisite to relax and extend the large mass of glutei and other pelvic muscles.

It has been thought by some surgeons, and perhaps with justice, that continuous, warm, moist applications have an effect in relaxing and weakening the muscular fibre. How deep the influence of such applications extends from the surface may be a question. In order to omit no measure, however apparently trifling, which might be supposed to assist to the end in view, I commenced with warm poultices. These enveloped the pelvis and hips, and were renewed twice a day for one week.

January 6, 1883, a firm leather belt three inches wide, padded and lined with chamois-skin, was buckled round the hips. To the upper edge of this belt four long straps were attached, extending from just above the anterior superior spinous process of the ilium on each side in front and from just above the sacro-iliac synchondrosis on each side at the back. These long straps were buckled to the rail at the head of the iron bedstead. Two perineal straps were fastened by four buckles to the lower edge of this belt, in such a manner as to bring the soft, padded portion into the groove of the groin. This gave a perfectly firm, unyielding counter-extension.

Direct extension was made by means of stiff leather bands, three and a half inches wide, padded and lined, encircling the legs above the knees and above the ankles, accurately fitted. To the lower edge of the bands leather loops three or four inches long were fastened, one on each side. A cord to which weights were suspended passed over parallel pulleys at the foot and on a level with the bed, and were tied to the loops. See *a, a*, plate 3, and *a, a*, plate 4. The use of the bands alternated: sometimes those above the knees, and sometimes those above the ankles, were employed. In this way the pressure around the limbs could be frequently varied, thereby affording great relief.

It is important to be thus minute in relation to Plates Nos. 1 and 2 are from photographs of a former patient, a complete facsimile of the one I am now describing. On comparing these photographs with the subject of this paper, at my first examination, April 1, 1883, they were deemed, both by the parents and myself, to be exact representations of the case before us and no others were considered necessary.

the various appliances, as all expectation of success depends upon their being rendered as little painful and irksome as possible.

The knee-bands were preferably employed. By them the extension drew directly upon the pelvic muscles. The object here being to tire out and to permanently stretch these organs, and thereby remove one important obstacle to restoration. Weights weighing three pounds were used at first. These were afterward increased. After a few days the head of the bedstead was raised by means of wooden blocks, eight inches high. The child was thus, to a certain extent, suspended by the perineal straps.

In the course of ten or twelve days sufficient relaxation of the muscles was produced to allow of easy manipulation of the bones, and each morning they were placed in their natural position, where they were maintained by the weights for some hours. On the following morning, however, they were invariably found displaced. About this time, on two or three occasions when drawing upon and rotating the left femur, a sensation was communicated to the hand as if the head of the bone was passing over an inequality. Whether this sensation was due to its slipping over a segment of the rim of an undeveloped acetabulum, or whether it arose from its passing over a portion of an elongated round ligament was a question which was difficult to decide. I was disposed to think that the former supposition was correct. Dr. H. H. A. Beach, when examining the patient at this time, also detected this slight jar on rotating the left femur, previous to the upward movement by which it passed on to the dorsum ili, and was inclined to the opinion that such a segment as above suggested did exist.<sup>2</sup>

This inequality was at no time observed on the other side, and even here could not always be discovered.

If a detached remnant of the cotyloid ligament did exist, it was so imperfect as to offer no resistance to the free movements of the head of the femur, and escaped detection at the earlier examinations.

About the middle of February it was found that the tendency to slip upward was greatly diminished, and that days elapsed without this occurrence taking place.

Accurate measurements, together with the hint derived from the slight section of a ridge on the left side just referred to, were the guides for placing the heads of the femurs and electing the spot for the formation of the hoped-for sockets.

As an assistance to this end I resorted to a position of the limb which I had seen employed by Dr. H. J. Bigelow in a case of acquired hip dislocation which in facility of displacement resembled the one we are now considering. This position was likewise resorted to in a case which is narrated in his work on "The Hip," and is described on page 56.

The case was one of traumatic dislocation of the hip of eight months' standing. The limb was reduced by flexion, abduction, and eversion, but was readily displaced. Dr. Bigelow says:—

"A very slight inversion sufficed to reproduce the dislocation; in fact, the limb could not be

trusted to itself. After the bone had thus repeatedly slipped out, the patient was placed in bed on her back, and the dislocation again reduced by flexion, abduction, and eversion, which brought the flexed thigh and knee down to the mattress on their outer side. The knee was then tied to the bedstead in this position by a towel, and the foot secured to the knee of the sound side until the socket should be excavated by absorption."<sup>10</sup>

To return to my patient. The femoral heads now being in normal position the thighs were flexed to nearly right angles with the body and then spread in the manner described by Dr. Bigelow, and the knees tied to the edge of the bedstead on each side and the feet secured to the opposite side. The heads of both thigh-bones were thus brought to bear forcibly on the pelvis at the points selected, trusting that absorption might be produced as a commencement of the desired depression.

This position was painful and could be borne but two or three hours in the course of the day. The strain on the anterior crural and other nerves in the neighborhood affected the whole nervous system. After the ties were removed from the knees the legs were weighted as before and so remained the rest of the twenty-four hours. The traction bands were alternated, as previously mentioned, from those that encircled above the knees and those encircling the ankles.

Two long narrow strips of wood were now attached to the foot of the bedstead a few inches from the corners. (See *b, b*, plate 3, and *b, b*, plate 4.) Near the top of each a pulley was inserted twenty-seven inches from the mattress. Cords were tied to the loops of the encircling knee-bands and run through these pulleys, to each of which was suspended a three-pound weight. This was traction on a line opposed to the dislocation, namely, forward and downward, and was alternated with the parallel extension, one or the other being used day and night. At no time were the limbs allowed, even for a moment, without extension. When the bands were changed from knees to ankles, and *vice versa*, an assistant always held the limbs firmly extended until the weights were reapplied. This manual traction was likewise maintained when the patient was temporarily moved to another bed. The three-inch wide pelvic belt, previously described, was constantly worn, and beneath it, on each side, narrow, firm, graduated compresses, made of soft linen, were placed across the dorsum ili, immediately above the trochanter major. One of the compresses was nine inches long, four and a half wide, and a quarter of an inch thick; the other, five and a half inches long, five inches wide, and a quarter of an inch thick.

By means of this belt and compresses pressure was maintained with the object of obliterating the sacs in which the bones had played.

The limbs were now rarely displaced. All the unavoidable movements attendant on change of apparatus, etc., were borne without injury, indicating that the heads of the thigh-bones were to a very considerable extent secured in their new position.

Thus much having been gained, the next object was by passive flexion and extension, in imitation

<sup>2</sup> I will here mention that Drs. J. C. Warren and H. H. A. Beach saw this patient at intervals during the course of the treatment, and later Dr. F. W. Cheever also examined her from time to time.

<sup>10</sup> The Hip, p. 56.

of the natural motions of the joints, to still further promote absorption, and perhaps cause some degree of irritation in the immediate neighborhood, and consequent effusion of adhesive matter.

To accomplish this three sets of pulleys were employed, namely, the parallel at the foot of the bed (*a, a*, plate 3, *a, a*, plate 4), the high ones at the foot of the bed (*b, b*, plate 3, *b, b*, plate 4), and two additional pulleys at the head of the bed (*c, c*, plate 3, *c, c*, plate 4). The high pulleys (*b, b*, *b, b*) were used, as before, for oblique traction from the knee-bands. The cords from the high pulleys (*c, c, c, c*) were likewise attached to the knee-bands in front. To this a light weight was suspended, which served as a handle, and when drawn upon raised the thigh to an angle with the body. The cords over the parallel pulleys (*a, a, a, a*) were tied posteriorly to a soft roll of padded linen, which passed round the upper extremity of the thigh. When the joint was flexed to an obtuse, or right, angle by drawing down the weight on pulley *c, c, c, c*, it is evident that the weight on *a, a, a, a* acted upon the femur as upon the extremity of a lever, preventing the head from rising when the upper pulleys (*c, c, c, c*) were in action. It will be seen that by this arrangement we have flexion and extension of the articulation, with every safeguard against displacement. An attendant stood, or was seated, at the head of the bed and drew the small weight downward, by which action the knee was raised toward the abdomen. The weights at the foot then pulled it back again. At the same time the pelvic leather belt buckled over the summits of the trochanters caused strong pressure against the pelvis. Four hours a day this passive exercise was continued, two hours for each limb. This may properly be termed the stage of excavation. The blocks from beneath the legs at the head of the bed were placed under the foot. The trunk then served as counter-extension. The long straps were removed from the head-rail. As an additional security a belt eight inches wide, made of soft, pliable leather lined with thin leather, and cut going to fit the hips, was used outside of the narrow belt. This wide belt had five small buckles and straps or billets of webbing, each one and a half inch wide, and round, padded perineal straps. The wide belt encroached somewhat on the upper part of the thighs, and a slit was required for the passage of the perineal straps to buckles in front. During the passive exercise the outer belt was removed. The course I have here indicated was pursued, with slight variations, until July 20, 1883. The time allotted for exercise had been gradually lessened. The high pulleys at the foot were used one day and night. The next day and night the patient wore the wide belt, thus alternating from one to the other.

The hips remained in position. The last time either had been displaced was on March 28, 1883.

June 2, 1883. The patient was removed to the seaside to a hotel in the neighborhood of my summer residence. Every precaution was observed in the removal. She wore the narrow belt, with the compresses above the trochanters, and the wide belt over it. She was placed in a hospital basket. The long straps from the narrow belt were secured to the head end of the basket. The perineal straps

were buckled in place. The straps from the knee-bands were fastened to the lower end of the basket.

In this way the patient was made a solid fixture to the basket, and could be moved in any way without disturbing her position. She arrived safely at her destination. This same arrangement was used through the summer. By it she was enabled to be upon the piazza or beneath the shade of the trees almost daily.

As an indication of the firmness with which the bones were held in their new position, I will mention that on one occasion much alarm was caused by the child rolling out of bed in the night. When reached, her head and hands were upon the floor, and her body was suspended obliquely by the foot-weights, which brought up against the bed-rail. No injury arose from this accident.

July 20, 1883. The first attempt was made to test the strength of the tissues by which the heads of the femurs were retained in their sockets. I pushed the limbs upward, and then upward and backward, with considerable force. There was firm resistance in each direction. From this date this experiment was frequently renewed, more and more forcibly, until finally the body was moved by pushing against the rim of the acetabulum, which was now unquestionably formed.

Dr. Beach saw the patient again in October, 1883, after her return to Boston. He judged that the upward pressure thus employed would amount, calculated by pounds, to more than the weight of the child. The patient now used active movements of the limbs in imitation of the previous passive exercise with weights. In order to avoid the friction of the foot upon the bed the heel rested in the hand of an attendant in its to-and-fro movement. This was done with a weight of two pounds attached to the ankle, for five minutes, twice a day.

Dr. D. W. Cheever, at my request, examined the patient at this time and freely manipulated the limbs.

The fourteenth day of January, 1884, the little girl sat up in bed, for the first time for thirteen months.

The period had now arrived for an initiation into the so long forbidden and forgotten faculty of locomotion.

A cart was constructed, of which plate 5 is a representation. It is very simple in its make, and perfectly answered its purpose. The plate requires but little explanation.

The heavy leather strap with the saddle in the centre is the important feature. The patient sat astride upon the saddle, which when first used was buckled upon the cross-bars, at such a height as only to allow the extremity of the toes to touch the floor. The crutches, as is plainly seen, were made to slide up and down and fixed by thumb-screws. They were of elastic wood and were sprung into and fitted the axillæ, where they were secured by a webbing belt. They relieved the perineum of a portion of the weight. From time to time the saddle and the crutches were let down until she walked squarely upon her feet.

At first she only imitated walking, but soon was able to propel herself through two large rooms and a hall with ease. The hip-joints worked perfectly.

As a safeguard against accidents the narrow leather belt was still worn. In April the patient bore her own weight for a few moments at a time, and on the 11th took her first drive sitting up. May 14th she began to walk in her carriage, without the saddle, and on the 16th without either saddle or crutches, taking hold of the side-bars. On the 18th she walked, supported on each side by a person holding a towel which was passed through a loop in a belt around her waist, steadying herself by grasping a cane held above and in front. I will here quote a few minutes from a journal kept by the patient's mother, of which I have availed myself for many of the data in the previous pages.

It is right to add that to her faithful, unwearied, and determined perseverance the success which has attended the case may to a great extent be attributed.

Note for June 9, 1884. "While sitting in her chair, got off the chair, turned round, and stood up; turned round, then turning back again, sat down.

"June 11th. Walked by herself without support a distance of three feet. Did this six times.

"June 12th. Walked twelve times without support, the distance being a little greater.

"June 19th. Having more confidence in herself she walked about the room alone.

"June 24th. Light corsets with steel ribs instead of whalebone were put on to support the spine, which seemed weak.

"June 28th. Commenced to use canes, which gave her confidence in walking."

On the thirtieth of June, 1884, the patient left Boston for her home in the southern part of the State.

It is worthy of remark that the patient, with slight exceptions, remained in excellent health throughout the long confinement, was always in good spirits, retaining her flesh and a healthy color in her cheeks. On account of her appreciation of the importance to herself of the course pursued, she much facilitated the treatment.

Plate 6 is from a photograph taken just before leaving the city. It is a back view. The child is reclining on her left side to show the hip and the symmetrical outline of the body at this period.

My later notes of the case are as follows:—

January 20, 1885. The child walks well without canes. There is some lateral movement of the shoulders due to spinal debility which is probably the result of long continuance in the horizontal position. The left knee obliques slightly inward, causing the limb to appear somewhat shorter than the right and producing some inequality in her gait.

February 18, 1885. The walk has much improved, partly in consequence of shoes being worn, which support the weak ankles. There is some degree of muscular atrophy between the trochanter and the crest of the ilium, on each side, where formerly rested the femoral-heads. This depression is also due in part to the pressure of the belt and compresses. The limbs can be pushed upward, and upward and backward, against the lips of the newly formed acetabula with a force which rolls the pelvis, and moves the body without the slightest displacement.

March 23, 1885. The lateral movement of the

shoulders disappeared some weeks since. As strength has increased the left knee has become nearly straight. The tread is firmer and more even.

Nélaton's line, passing over the summits of the trochanters, indicates that the heads of the femurs are in their normal position. They have not been displaced since March 28, 1883.

May 25, 1885. The child's walk is normal, and she enjoys walking; she steps with natural firmness and vigor. Like other children she takes especial pleasure in running.

The photographs from which the two pictures composing plates 7 and 8 were reproduced were taken March 23, 1885, about two years and three months from the commencement of treatment. The first figure, plate 7, is standing in a position to correspond with the figure in plate 1, which latter gives a side view previous to treatment. Plate 8 is a front view to correspond with the second figure of the series seen in plate 2.<sup>11</sup>

## THE SELECTION OF A SUITABLE CLIMATE FOR THE VARIOUS FORMS OF PULMONARY CONSUMPTION.<sup>1</sup>

BY J. HILGARD TYNDALE, M.D., OF NEW YORK.

The law of the beneficial influence of climate in pulmonary consumption may be remembered by this adaptation of a biblical phrase: *There abideth equability, dryness, and elevation, these three; but the greatest of these is dryness.*

The following tables will serve as a guide to the various degrees and qualities of climatic constituents. The humidity table is R. v. Vuietot's; the rest are my own.

### TABLES OF THE CONSTITUENTS OF CLIMATE:

Humidity, equability, elevation, and degrees of warmth.

#### (1) Humidity.

Excessively dry: 1 to 55 % of relative humidity.  
Moderately dry: 56 to 70 % of relative humidity.  
Moderately moist: 71 to 85 % of relative humidity.

Excessively moist: 86 to 100 % of relative humidity.

#### (2) Equability.

Very equable: 15° to 35° of monthly range.  
Moderately equable: 36° to 50° of monthly range.  
Unequable: 51° to 65° of monthly range.  
Very unequable: 66° to 85° of monthly range.

#### (3) Elevation.

Low altitude: 500 to 1,000 feet above sea-level.  
Moderate altitude: 1,100 to 2,000 feet above sea-level.  
Medium altitude: 2,100 to 4,000 feet above sea-level.  
High altitude: 4,100 to 7,000 feet above sea-level.

#### (4) Temperature.

Hot: 80° to 100° of monthly mean.  
Warm: 55° to 79° of monthly mean.

<sup>11</sup> The illustrations which accompany this paper are exact reproductions of the original photographs by a new application of the gelatine process, which preserves great delicacy of detail and outline.

<sup>1</sup> Concluded from p. 517.

Cool: 54° to 30° of monthly mean.

Cold: 29° to 0° of monthly mean.

The annexed tables of meteorological data of various stations throughout the United States have been kindly furnished me by the Chief Signal Officer. The localities named are not the best health stations, as comparatively few of the latter are supplied with signal stations. The list is intended to illustrate the various climates of this country, where equability with various degrees of temperature, from hot to cold, exist, as well as dryness with various degrees of altitude.

(1) *Equability.*

Stations along the coast of the Atlantic and Pacific Oceans and the Gulf of Mexico.

(a) COLD: SUMMER AND WINTER.

THE NECESSITY OF ADMITTING A VITAL PRINCIPLE.<sup>1</sup>

BY THOMAS DWIGHT, M.D.,

Parkman Professor of Anatomy at Harvard University.

To the student whose ideas of philosophy have been gained, not only from so-called popular science, but from the teaching of many men eminent for their knowledge, a vital principle seems useless, even absurd. In fact there is something comical in the surprise with which young men whose teaching has been solely materialistic learn that any one of any scientific attainment should presume to defend it.

I propose to show that it is reasonable and even inevitable to admit a vital principle, and this by three distinct arguments, each based upon observation.

The first is that in every living organism, vegetable or animal, something non-material is necessary to give the matter unity.

In a plant or animal we see a process of growth

<sup>1</sup> Read before the Boston Society of the Medical Sciences, April 28, 1888.

that is essentially different from mere increase of bulk. The organism does not increase as a whole, but each part increases at a different rate, depending on the needs of the individual and undergoing waste in some cases, while the whole is still growing. Not to spend time in giving examples, which are easily found, I would mention only the reproductive functions by which animals of the same kind as the parent are reproduced. Now it is evident that the living organism is one in a very different sense from that in which a heap of sand is one or a wave is one. You can add and subtract sand or water and the accumulation becomes larger or smaller, and in the same way the living organism can take in or give out matter without its oneness being disturbed. But what makes the animal one? It is clearly that principle which so regulates its nutrition that each part grows at its proper rate, aids the others, dwindles when its work is over, and, in short, forms a harmonious whole. Now there is absolutely nothing that we know of in matter that can bring this about.

The force of the spring that keeps a watch in motion has no power similar to that by which growth is determined, which in some animals leads to the perfect reproduction of lost parts and in all tends to repair injuries so as to maintain function. A recent example of this is the observation of Roux that the ankylosed bones of a knee had a new spongy formation suited to their new demands.

There certainly is some such power. It is found only in living organisms, and therefore has been named the vital principle.

The second argument is the theory of sensation. It seems from what we know of matter that it is impossible for it to feel. Let us suppose that an impression being made on each of a group of nerve cells each one enters into the impressed condition and feels the impression made upon it. Let it be said in parenthesis that it is entirely an assumption that the impression is tantamount to feeling, but supposing that to be the case it is evident each cell can feel only the impression made upon itself and can know nothing of the impressions made on its neighbors. It is as if each member of an audience heard one note of an air, or as if each element of the retina saw what came in the ray of light falling on it, and that alone. To say that the impressions are concentrated on a smaller group of cells does not help us out of the difficulty, for even if we finally brought the nerves to a single cell, even that cell, being extended, has parts, and each can perceive only the impression made on itself. Evidently, then, there must be a non-material unextended element which, governed by other laws, can feel the impression as a whole.

The third argument consists in the freedom of the will. We shall consider this solely in man, because the argument is based on our own consciousness. All we know of the laws of matter tends to show that a given cause, acting under similar circumstances, produces inevitably the same results. Were it otherwise, there would be no physical law. It has been asserted that man in the same way unconsciously follows the strongest impulse, but all that is needed to refute this is unprejudiced introspection. If we suddenly touch what hurts us we

instinctively withdraw the hand, but we know that by strength of will the shrinking can be overcome. A very striking example of the freedom of the will is the ability to choose to which of two sounds the attention shall be given. It is of daily observation that it is possible for us to direct the attention to a lecture while a band is playing or to neglect the lecture to listen to the band. We may even, by force of attention, become unconscious of distracting noises, even loud ones. Clearly we could not do so were material forces the only ones at work. Those who deny this maintain a proposition that every action of their daily lives contradicts. What sane man doubts that it is in his power to go up or down the street as he sees fit? If we deny the truth of our consciousness in this matter what possible criterion of certainty can we have? On what premises can we base any argument whatever?

I will now present a short extract from an address by Dr. Hammond, on the "Relations of the mind and the nervous system," published in the *Popular Science Monthly* of November, 1884. I do so because it is a typical specimen of much that unfortunately passes for science. He is at particular pains to state that by mind he does not mean soul: "With it (the soul), however, I conceive we have nothing to do, as far as science goes. Its very existence is a matter of faith in which, probably, most of us believe, but which is altogether beyond the limits of proof or even of investigation. There is nothing tangible about it. We should not know how to proceed to ascertain the existence of the soul." Dr. Hammond would do well to speak for himself; I submit that the preceding observations establish it perfectly. He states a little later that one "could not say that life is the soul, for if he did he would have to accord souls to all living beings, vegetable as well as animal. And if he declare that the mind and soul are identical, he would be obliged to admit that the 'beasts that perish,' and even the vine that creeps up the side of his house and finds out where the supports are situated around which it sends its tendrils, have souls which, if not as perfect as his own, are none the less real." Even so. There can be no doubt of it; but by using the word "soul" Professor Hammond makes what is perfectly true appear absurd to those of the modern school. I have purposely avoided the word and limited myself to showing that there must be a non-material principle. I do not intend to discuss in this paper the nature of the vital principle in the different orders of living beings, but merely to show that there is one.

Dr. Hammond commits here the error of assuming that he has made a *reductio ad absurdum* when he has done nothing of the kind; but we now come to a grosser blunder: "If the mind and the soul are identical, all these predisposing causes, if inherent in the parents, and which are capable of causing imbecility and idiocy in the offspring, are also capable of damaging the immortal soul that we believe God has given to every human being. The little piece of bone of a fractured skull that, pressing upon the brain, stupifies the mind, at the same time damages the soul; the congestion or inflammation of the brain that converts a man of giant intellect

into a mania or a dement beyond a hope of cure, also irreparably ruins the soul, which, we are told, never dies; and which, if it exists, is doubtless far removed from the influence of bodily diseases or injuries."

One would be inclined to think that overmuch popular science had undermined the author's respect for his audience, for how else could he have ventured to commit such reasoning to the permanent keeping of type? If a wheel in the machinery is broken and, instead of producing, it destroys, we are then to infer that the steam is at fault. Or if bad butter is put into the cake, that the other ingredients are bad because the result is so. And this is what is palmed off upon us as science! The soul works through the body. If the instrument is diseased or imperfect it cannot work well; but what right has any one to say that the soul is injured? If dust is in the eye vision is disturbed, but it is the organ and not the sentient power that suffers.

## Reports of Societies.

### AMERICAN CLIMATOLOGICAL ASSOCIATION.

SECOND annual session, May 27 and 28, 1885. Held at the Academy of Medicine, New York.

Afternoon session, May 28th. The President, A. L. LOOMIS, M.D., in the chair.

#### THE PRESIDENT'S ADDRESS.

After briefly referring to the general purposes for which the Association was formed, the President said that he advocated a broader scope of work, and would include observations as to the influence of climate upon the vascular system and the therapeutic value of our mineral springs. It was hardly necessary for him to review the attention which had been given to the therapeutic value of mineral springs in Europe; it was evident from the benefit derived from them that they were either superior to those of our own country or that the profession there knew better where to send their patients. Dr. Loomis felt convinced from a careful study of the subject that neither the climate nor the mineral waters at these health resorts in Europe were superior, as a rule, to those of our own, and that the greater benefit which patients derived from them was due to a better knowledge on the part of the medical profession of their therapeutic effects. It was only within a few years that we had made any systematic attempt to determine the value of our mineral springs and the influence of their climate.

Dr. Loomis advocated the building of sanitarium at mineral springs and other health resorts where the poor might experience their advantages without undue expense. The practicability and value of this suggestion was illustrated in the sanitarium built in the Adirondacks where many consumptive patients resorted for their health. The cottage form had there been adopted, and so arranged that additions could be made from time to time to meet increased demands. The buildings were situated in a suitable locality where there was sunshine, a sandy soil, and other conditions promoting a dry atmosphere. It was not difficult to get a number of benevolent

people in the neighborhood to take an active interest in the undertaking, and there were those who would give medical aid. The cost at present at the sanitarium in the Adirondacks was five dollars a week. Dr. Loomis asked if we were not justified in hoping that in the near future this Association would become the centre of information concerning the therapeutics of the respiratory organs, and with this object in view he suggested that medical politics and extraneous matters be excluded, and that it be made a truly scientific society.

A few words with regard to the aetiology and morbid anatomy of pulmonary phthisis, and its climatic treatment. Whatever conclusions might finally be reached concerning the exact cause of the different varieties of phthisis, he thought that clinically we might speak of the disease as acute or chronic. Tubercle might, or it might not, be the primary lesion, but it was usually present in the advanced stage; he was not prepared to say that tubercle was the primary lesion in all or in very many cases; when it was not the primary lesion there was a preceding condition which prepared the ground for the development of tubercle. If it should be shown that phthisis had its origin in infection, clinical observation still showed, he thought, that there must be a preparatory change in the lung tissue before the infective element could be received. Both experiment and observation seemed to show that bacilli, whether developed inside or outside of the body, could not thrive unless certain favorable conditions were present. The crucial test regarding the aetiology must be a clinical one. By this standard there were three factors which might be regarded as preparatory to the phthisical infection, if an infection should be found to exist: First, a stage of constitutional feebleness which diminished the resisting power of the individual and rendered him abnormally susceptible to diseased process; second, a condition of the upper portion of the lungs marked by feebleness and slowing of the circulation; third, the establishment of a localized inflammatory process in the bronchi, lung substance, or pleura.

Dr. Loomis thought that no one would question that the treatment of phthisis which was attended by the best result was that which had for its object the invigorating by every means possible the general health, and avoiding those conditions which favored local pulmonary induration. A suitable climate acted therapeutically to arrest the phthisical process in two ways: First, by its invigorating effect on the general system and improving nutrition; and second, by its effect on the diseased lung in a way to prevent or arrest the diseased process. Dr. Loomis then asked the question: What are we to understand by the term "climate"? and said that to assume that any particular climate exercised a specific influence upon phthisis was absurd. That certain climates, however, were better for the phthisical than others was beyond doubt, but as to what climatic constituents made the difference there was great diversity of opinion, a fact which constituted one of the fundamental difficulties in the climate problem. Purity of the atmosphere and consequent freedom from germs seemed to Dr. Loomis the most satisfactory solution of the vexed problem of climatic influence. Purity of atmosphere had the thera-

peutic value of elevated regions, but all elevated regions did not have purity of atmosphere. Moisture favored phthisis, and a moist atmosphere was laden with germs; dampness was due largely to the peculiarity and formation of the soil; it existed in all clay regions. Frequent showers undoubtedly purified the atmosphere where the soil favored free drainage. The air of a locality might not be impure if ozone were absent, yet the presence of ozone was presumable evidence that the air was optically pure.

Dr. Loomis was convinced from many observations that the tubercle bacillus was always present in the sputa of patients in whom the phthisical process had advanced to a recognizable stage, and the question would naturally arise, if they were promotive of the phthisical process, how might their entrance into the lungs be avoided, or, if inspired, how might their increase be best prevented. But clinical observation had not shown that inhalations diminished their number; if inhalations were beneficial, the effect was wrought upon the mucous membrane of the upper air-passages, and not upon the diseased lung substance. But that there was some intimate connection between the development of phthisis and atmospheric impurities clinical observation seemed to have proved, but as yet bacteriology had not determined what one of the many minute organisms which had been described, or which existed, was the cause of the trouble. Dr. Loomis mentioned some cases which went to prove that the tubercle bacillus disappeared from the sputa of the phthisical patient because of a change to an atmosphere unfavorable to the bacillus and where the patient's condition improved.

Dr. Loomis advised the trial of a station near the patient's home, before going a long distance in search of a climate favorable for the consumptive, especially so in the active stage, and he would never send a patient with advanced phthisis far from home in search of health. If a given place were found advantageous, let the patient remain there until well advanced toward recovery or until recovery was complete.

"The Climate of Mexico," by H. D. Didama, M.D., was read by title.

#### ANTISEPTIC INHALATIONS.

Dr. BEVERLY ROBINSON, of New York, read the paper, which he said was based upon clinical observations. He believed that inhalations were useful, notwithstanding any theories to the contrary. He would not limit his remarks solely to the value of inhalations in phthisis. The facts in favor of the practice were as follows: (1) The inhaling apparatus costs but little; (2) it might be used where hot or cold sprays were impracticable; (3) there was no risk of future exposure to colds attending its employment; (4) the relief afforded by dry inhalations was frequently greater than that afforded by other methods of inhalation; (5) it was adapted to all forms of disease of the respiratory tract. There was but one serious objection to its use, namely, it was claimed that the vapors of volatile and antiseptic substances did not penetrate far enough to reach the pulmonary cells. A sufficient answer to this objection was the fact that patients after using the

inhalations for some days or weeks say that their subjective symptoms have been relieved, that the sputa has been diminished in quantity and at times notably changed in appearance. Again, Dr. Robinson said that dry inhalations did penetrate farther than the spray for which they were substituted, and he thought they permeated to some extent the air-cells. Besides, from his observations he was led to believe that the chief lung area from which cough proceeded was the apex.

Proceeding to his clinical experience, Dr. Robinson had employed inhalations altogether in seventy-six cases, twenty-two of which were cases of phthisis; the others were divided among bronchitis, laryngitis, laryngeal phthisis, nasal catarrh, etc. The substances employed for inhalation were, alcohol, creasote, compound tincture of benzoin, firwood oil, chloroform, turpentine, the volatile oils, carbonate of magnesium, etc., either singly or in combination. The most useful inhalation in beginning phthisis was creasote and alcohol in equal parts, from ten to twenty drops being employed two or three times in the twenty-four hours. Ten minutes was the usual length of time of inhalation, although half an hour might be occupied. The best and cheapest inhaler was made of perforated zinc.

The results which he had observed were, that the patients experienced less difficulty in breathing, their cough was improved, the sputa diminished in quantity, they were better able to sleep, and their general condition was likely to improve; one patient gained in weight. As to the influence of the inhalation upon the tubercle bacillus, he had not made special observations. In one instance his house physician noticed an equal number of the bacilli before and after the use of the inhalation. Notwithstanding the patient's rational symptoms were improved, taking all of the cases into consideration, firwood oil had proved of greatest benefit.

Dr. F. C. SHATTUCK, of Boston, said that some years ago he employed carbolic acid in some of these cases, but the patients found its inhalation to be extremely disagreeable. Perhaps he used it too strong, and under other circumstances the patients may have taken more kindly to it. Certainly it was very desirable to give something which would allay cough, for cough constituted hard work even for a healthy person. It would be of special advantage if it would enable us to dispense with opium. The observations which had been made with this method of inhalation which showed that two thirds of the substance employed could afterward be found still remaining in the sponge, gave reason to suppose that very little of it reached the lung tissue, and would tend to throw distrust upon the treatment.

Dr. REED asked whether ether and cocaine had been employed by Dr. Robinson. Cocaine applied to the larynx would tend to relieve cough.

Dr. KRETZSCHMAR, of Brooklyn, thought from Dr. Robinson's own conclusions that it could not be claimed that the air-cells had been affected by the substance inhaled.

Dr. WESTBROOK thought the benefit observed could be referred to two influences: first, the favorable influence upon the upper respiratory mucous membrane of an atmosphere kept constantly at an

equable temperature. Besides, the balsamic vapors which were usually employed, if used for a time, had a soothing effect upon the mucous membrane and tended to allay irritation of the upper air-tract where cough generally had its seat of excitement. Allaying cough, the patient got more rest, slept better, and gained in bodily condition. Again, cod-liver oil, malt, etc. had been administered. He did not think that irritation at the apex of the lung was more likely to produce cough than irritation of any other portion of the lung.

The PRESIDENT remarked that the violent paroxysms of coughing in phthisis were very commonly the result of pleuritic adhesions, both in stages where but few physical signs might be present and in the advanced stage. His experience with inhalations led him to believe that they did good so far as they acted as anodynes to the upper air-passages, and no farther. He perhaps was prejudiced against them, for his experience had been unfortunate; they had in several instances been followed by profuse hæmoptysis.

Dr. ROBINSON, in closing the discussion, said he had on one or two occasions employed ether, but it seemed to be irritative. He had not employed cocaine in this manner because he could not see how it could be of any benefit.

#### CATARRAL AFFECTIONS OF THE NASAL CAVITIES AS A CAUSE OF PULMONARY PHTHISIS.

Dr. W. C. JARVIS, of New York, read the paper, and said he might add to the title, "With special reference to heredity." He first directed attention to the views of Koch and others who had pointed out the conditions which most favored the development of the tubercle bacillus, and said that, in his opinion, that state of the upper air-passages which existed in catarrhal affections, and was brought about by conditions which he would proceed to mention, best fulfilled the conditions indicated. Dr. Jarvis then referred at considerable length to views which he had previously published, concerning the effect of the nasal mucus in disease upon the laryngeal mucous membrane, to the causes of nasal catarrh, and especially to the influence exerted in its production by deflection of the nasal septum, and to heredity as a cause of said deflection. His opinion, in short, was that marked abrupt elevation of the central portion of the arch of the palate, which was likely to be hereditary, was a frequent cause of deflection of the nasal septum.

Dr. REED had been interested in the paper, but he could not regard it as demonstrated that there was any marked causative relation of nasal catarrh to pulmonary phthisis.

Dr. ROBINSON did not wish to criticize the paper, but he thought the title was hardly a suitable one. He would leave off the latter portion of it, "as a cause of pulmonary phthisis." He had not been able to trace pulmonary phthisis to catarrhal affections of the nose.

Dr. GOODWILLIE, of New York, had seen and modeled a great many mouths, but, as to the height of the palate, it might be only apparent; the alveolar regions might be fuller, making the palate seem very high.

Dr. JARVIS closed the discussion, and said he

thought it was unnecessary for him to offer proof of the connection between nasal catarrh and pulmonary phthisis. It was spoken of by Niemeyer and Billroth, and he supposed it was generally conceded. As to the form of the palate referred to, he directed Dr. Goodwillie's attention to the fact that it was the abrupt elevation of the central portion which caused displacement of the nasal septum.

Dr. ROBINSON remarked that he was not aware that either Niemeyer or Billroth were much in the habit of looking into nostrils.

(To be concluded.)

#### CHICAGO MEDICAL SOCIETY.

REGULAR stated meeting, February 2, 1885; Dr. STEELE in the chair.

A paper upon

PEROXIDE OF HYDROGEN AS A MEDICINE: ITS USE IN AURAL AND OPHTHALMIC PRACTICE

was read by Dr. BOREUS BETTMAN.

He stated that the antiseptic measures introduced by Lister had been applied in aural therapeutics and marked the era of rational medication. Carbolic acid, although highly satisfactory as a cleansing agent, could not be applied as a germicide. A five per cent. solution could not be tolerated by the sensitive mucous membrane. The boracic-acid treatment was alluded to as finding many advocates and it had well sustained the severe tests to which it had been subjected.

Bichloride of mercury and iodoform were next dwelt upon, and the happy results achieved by their use. He then spoke of peroxide of hydrogen as a remedy efficient and useful in cases where a number of other antiseptic remedies had failed to perform their work. This article was discovered by Thenard in 1818, and introduced into medical literature by Dr. B. W. Richardson, of London, in 1855. It soon fell into disuse and had apparently become entirely forgotten, but lately it had been reclaimed to the medical world by the unceasing labors of Dr. Collin, of various Parisian surgeons, and of Dr. A. W. Harlan, of this city. The remedy has been principally employed by dentists in the treatment of alveolar abscess.

Few allusions have been made to it in ophthalmic and aural literature. The usual method of preparing pure peroxide of hydrogen is by decomposing peroxide of barium with hydrochloric acid. In its pure state it is a colorless, syrupy liquid of a slightly bitter taste, and possesses a faint odor of chlorine. Its specific gravity is 1.455. It is a highly unstable compound and rapidly decomposes when exposed to air by liberating its oxygen. Regarding its value as a therapeutic agent it is due to this property substantially. M. Miguel, of the *Observatoire de Montsouris*, in his comparative table presenting the relative value of the various antiseptics, places peroxide of hydrogen at the head. The reader then gave some observations he had made with the microscope of its action on pus. The pus corpuscles and bacteria are put into lively motion, when a drop of the "peroxide" is allowed to flow under the cover of the glass. Small gas-bubbles, with the liberated nascent oxygen, are now evolved. The pus corpus-

cles lose their spherical form, shrink, assume a crescentic shape, and become "heaped" as a mass of detritus. The bacilli are affected in a similar manner. In a few seconds they are transformed into a dead mass, intermixed with the decomposed pus corpuscles, and surrounded by seething bubbles of gas.

**Therapeutical action.** The therapeutical action of peroxide of hydrogen has been explained as follows: When it comes in contact with pus, the extra oxygen it contains is liberated so rapidly that the hydrogen and sulphur of the tissues immediately combine, resulting in  $H_2 SO_4$  in small quantities, sufficient to glaze the pus-producing area, thus affording an opportunity for the exuding protoplasmic material to organize into new tissue. The remaining unsatisfied atoms of oxygen quickly distend the pus sack and force out the contents. The writer has used the remedy in more than thirty cases of otitis media purulenta, by employing a preparation containing twelve volumes of the gas according to the following method: The parts are thoroughly cleansed with tepid water, then dried with absorbent cotton, after which eight to twelve drops of the remedy are instilled into the ear; contact with pus and diseased tissues sets free the oxygen as visible bubbles, which, united with the expelled pus, forms a seething, frothy mass. Patients rarely complain of pain. After cleansing the parts the mucous membrane is seen to have assumed a milky-white appearance. The liberated gas enters the most hidden and remote recesses of the middle ear, forcibly dislodging the decomposing material, and destroying bacteria embedded in the tissue. If the perforation is small, the remedy can be injected directly into the middle ear. It has also been successfully used in the treatment of dacryocystitis and in one case of chronic trachoma which had run its course, but where there still remained a muoid discharge.

Five cases of dacryocystitis yielded to the peroxide of hydrogen, after having been subjected to the routine medication of carbolic acid, astringents, introduction of Bowman's probes, gelatine bougies, etc., etc.

In the discussion, DR. R. TILLEY stated that he had seen the peroxide of hydrogen solution used by Pagen, of Paris, as a spray in ovariectomy, and also by Landolt in dacryocystitis, but saw no manifest advantage from its use that should entitle it to preference over certain well-known and well-tried remedies, such as the solution of permanganate of potassa. In observations with the preparation it was of considerable importance to ascertain to what factor of the peroxide solution the alleged virtue was attributable; the peroxide of hydrogen solution is rendered more permanent by virtue of an acid, and the acid used is sometimes hydrochloric, and sometimes sulphuric acid; the former being more generally used. The quantity of acid is very small, but small as it is, it may have considerable influence. Minute quantities of sulphuric acid may have very deleterious effects in certain cases. The best test for the presence of the peroxide in solution is a crystal or two of permanganate of potassium.

DR. W. W. ALLPORT had used the remedy in treating alveolar abscesses and pulpless teeth, by

filling the cavity of a tooth with the solution; effervescence occurs and assists the cleansing of the cavity.

DR. J. S. MARSHALL has treated burrowing abscesses, when for obvious reasons he did not wish to make an external opening, by injecting a solution freely into such a cavity; the relief was, in his experience, much more rapid and satisfactory than with other agents.

DR. G. NEWKIRK had used it in cases which were not blind abscesses and obtained satisfaction. He found it difficult to obtain reliable specimens of the substance and to keep it perfect.

DR. BERTMAN acknowledged that it does not keep well, and that it is of importance to obtain a reliable article. He felt sure that the effect on the pus was due to the liberation of oxygen when it came in contact with the pus and its associated products.

#### MISSED ABORTION.

DR. P. O'CONNELL reported a case that he had treated, and then exhibited the pathological specimens, which consisted of a placenta and two foeti enclosed in the membranes, and having the appearance of a mummified-looking mass. It was about the size of a man's closed fist, and when expelled had a most sickening stench.

The patient was aged twenty-six, and had one child two years old. Three months after her last confinement the catamenia reappeared and continued regularly for some months, when this function ceased. In addition, the other usual symptoms of pregnancy were present. Three months from the commencement of pregnancy the patient fell, striking rather heavily on her hands and knees. A slight sanguineous vaginal discharge lasting a few hours followed. After this the abdomen, which had become considerably enlarged, slowly diminished to normal size, and her health slowly but steadily deteriorated. She had almost constant aching with occasionally severe pain, and a sensation of "going to sleep" in her left leg was experienced. Nor could she lie on her left side.

Careful palpation of the hypogastrium gave no evidence of uterine enlargement. The left inguinal region was tender on deep pressure. Upon making digital examination, *per vaginam*, the finger met the uterus fully an inch lower than normal with the os and cervical canal so patent as readily to admit the index finger. The anterior segment of the cervix was thickened. On bimanual examination the uterus was found a little enlarged but in no wise sensitive.

The sound penetrated to a depth of two and one-half inches and to the left. There was no hyperaesthesia of the vagina, although its mucous membrane was congested. The cervix was congested and bled readily and freely. She had but a slight leucorrhoeal discharge, which had no odor. Ergot and strychnia were prescribed. Soon after the first dose had been taken uterine contractions set in, ending in the expulsion of the mass, which had doubtless lain free *in utero* for three months. On close questioning the patient said that during August, which was extremely hot, she felt very cold during the night, so much so as to require heavy bedcoverings to keep warm. That she had frequent chills, and

once she had a well-marked rigor. These symptoms, with itching, an erratic rash on the the skin of the lower abdomen and back, general *malaise*, and slowly increasing debility, clearly point to the absorption of septic matter from the cavity of the uterus. The pain in the left lower extremity was due, of course, to the dead weight of the uterus on the branches of the sacral plexus of nerves.

A paper on the

#### TREATMENT OF CHRONIC BRONCHITIS AND ASTHMA WITH APOMORPHIA

was next read by DR. G. W. WEBSTER, who reported two cases he had treated with this remedy with much satisfaction, that did not yield to any other form of treatment:—

CASE I. MR. G., a native of England, thirty-four years old, married, and by occupation a carpenter. Had been in the United States about two years and three months. During the past summer, and especially at night, he suffered severely from spasmodic coughing. In December last, after trying many remedies, he had a severe cough with aggravated symptoms of asthma, and he had been for some days confined to the house and most of the time he was in bed. Apomorphia, in one-twentieth grain doses every three hours, was given him. After one day's treatment he passed a comfortable night. The remedy was then increased to one tenth of a grain three times a day, and the second night he rested well. The remedy was continued for two days longer, when he ceased taking it. The attacks recurred again but with much less severity; the drug was renewed three times a day for two weeks. He was able to be out and resumed his work most of this time, and the remedy was discontinued about four weeks ago, since which time there has been no return of the spasmodic coughing spells nor of the asthma.

CASE II. B., aged fifty-eight; laborer; has had chronic bronchitis with asthma every winter for many years. When called to see him a few weeks ago, found him suffering greatly from dyspnea; there were present râles over his entire chest. His face and hands presented a cyanotic appearance and he was gasping for breath. Gave the patient apomorphia, one twentieth of a grain every three hours. The subsequent day the patient was considerably relieved, and in another twenty-four hours he could breathe freely. The drug was continued a few days longer, in one-tenth grain doses *ter in die*; after which it was discontinued, and the patient has remained much better than for a long time.

DR. C. T. FENN reported an interesting case of "frostbite," and referred to the mismanagement of the case when first discovered, in which those who attempted to render assistance by rubbing with very cold snow and ice were also in danger. This portion of his paper related more particularly to errors committed by the laity in often using a valuable remedy injudiciously before the arrival of a physician.

The last three papers were briefly discussed mostly in the form of general remarks and conversation.

DR. R. E. STARKWEATHER presented to the members present a number of bound volumes of the Sixth Annual Report of the Illinois State Board of Health.

The Society then adjourned.

#### NEW YORK STATE MEDICAL ASSOCIATION.

##### FIFTH DISTRICT BRANCH.

SCIENTIFIC meeting, held at Poughkeepsie, May 19, 1885.

The President, DR. J. C. HUTCHINSON, of Brooklyn, not being able to be present, DR. J. G. PORTER, of Poughkeepsie, was called to the chair.

DR. JOSEPH D. BRYANT, of New York, read the first paper, on

#### THREE CASES OF LIGATION OF THE EXTERNAL CAROTID, IN TWO OF WHICH BOTH VESSELS WERE TIED SIMULTANEOUSLY.

The first of these ligations was in a case of aneurismal tumor situated in front of the left ear, of traumatic origin, but the relief was only temporary, and other measures had to be subsequently adopted for its cure. The other two operations, in which both the external carotids were tied simultaneously, were undertaken for the starvation of malignant growths. In the first of these cases there was an anomalous arrangement of the external carotid and its branches, the importance of which was not appreciated by Dr. Bryant at the time, and the patient, through the carelessness of the attendant, who did not discover the accident until too late, lost his life from hæmorrhage from the facial artery by reason of a slough at the seat of disease. In the other instance the operation had the effect of satisfactorily arresting the rapidity of the growth of the carcinoma.

The conclusions arrived at by Dr. Bryant were as follows:—

(1) That ligation of the external carotid artery, with independent ligation of its branches arising from the first inch of its trunk, is a safe and commendable operation.

(2) That when the facial and lingual arteries do not arise singly or by a common trunk from the first inch of its course, the branches arising at the bifurcation should be tied.

(3) That a simultaneous ligation of the external carotids is a rational preparatory measure to operations involving the parts supplied by their branches, when dangerous hæmorrhage is feared.

(4) That simultaneous ligation is advisable to diminish the rapidity of the development of extensive malignant growths when nourished by the branches of the external carotid.

(5) That the ligation of one or both external carotids for the cure of aneurismal formations of the branches of the same is not warranted as an independent measure.

(6) That ligation of the common carotid should not be done for the cure or for the arrest of morbid conditions involving the external carotid with its branches, except as a final resort.

DR. S. J. MURRAY, of Brooklyn, read a paper on

#### DIPHTHERIA AND ITS TREATMENT BY CALOMEL.

In 1857 diphtheria made its appearance almost simultaneously in England and in the extreme western part of the United States, and from that time had continued to appear in the form of epidemics of greater or less extent and severity, in the most varied climates and seasons, in almost all known parts of the globe. In regard to the epidemic, and

occasionally endemic, nature of the disease, he said, the evidence was plain; but it was still an open question as to how far it possessed contagious and infectious properties. That it was transmitted directly by contact with the morbid products generated by the local disorder he did not himself doubt. Its prevalence, and especially its virulence, was favored by defective drainage and contaminated air, and by the drinking of impure water. It was certain, however, that occasionally diphtheria appeared in a sporadic form, and that isolated cases sometimes occur which could be traced to no known cause whatever.

The large mortality in this disease, the death-rate sometimes running as high as fifty per cent., he thought, indicated that the best plan of treatment had not yet been adopted for it. He considered that the diphtheritic poisoning was effected in some way long before the disease was recognized by its local manifestations, and that it destroyed life, not by its local, but by its constitutional, effects. The remedy to which he wished to call special attention in connection with diphtheria was calomel. He was aware that it had already been employed to some extent in the disease, but it had been pretty generally condemned, he thought, as a dangerous agent. It was not, however, the legitimate use, but the abuse, of it, he believed, which had been followed by unpleasant effects. Dr. Thallon, in the paper read before the King's County Medical Society, in which he advocated the bichloride of mercury treatment, said that when the patient's bowels were constipated he gave the mild chloride. Might it not be that the success which he had reported was in part due to the latter? While others had used calomel for diphtheria, he knew of none that had used it in the same quantities that he had done. He did not adopt this plan of giving calomel in large doses, he said, until he had exhausted all, or nearly all, of the remedies prescribed by various authors, and when he commenced with it he resolved that he would give it a thorough trial.

Dr. Murray then reported in detail a number of cases in which he employed it, to show his plan of treatment. Thus, to a girl of ten years he gave ten grains of calomel, and to a boy of eight, eight grains of calomel, every four hours. He said that he always gave it dry, since when thus administered more or less of it lodged upon and around the membrane, acting as a solvent, and preventing its extension. He had never seen hemorrhage after the removal of the membrane, or the formation of a second membrane. Although the calomel acted as a sedative, it did not produce mercurialization or leave any unpleasant after-effects.

In the discussion which followed the reading of the paper, DR. ALFRED L. CARROLL, Secretary of the State Board of Health, said that unquestionably the cases reported by Dr. Murray recovered after the administration of calomel, but in listening to the paper a doubt had arisen in his mind as to whether the calomel was in reality the efficient agent in their cure. In the first cases described the sanitary condition of the premises was very bad, and the first thing that the speaker did was to remedy this. Now diphtheria was generally recognized as a

filth disease, and it was a fact that a large number of cases would recover without any medicinal treatment whatever if they were placed under good hygienic surroundings. Again, with the calomel, stimulus and nourishment were very freely given, and he had personally seen cases which recovered very rapidly under the use of stimulus and nourishment alone, without anything more in the way of drugs than an occasional dose of quinine. Fresh air, stimulus, and plenty of food were very potent factors in the successful treatment of diphtheria, and when these are all made use of it was not quite clear, he thought, how far the calomel had assisted in securing the good results noted. There were two other things which he had especially noticed in regard to diphtheria. The first was that the amount of exudation bore no positive relation to the severity of the disease in any given case; and the second that, in his own experience, at all events, the most rapidly fatal cases were those in which the temperature never rose above the normal, or, if it did so, soon became reduced.

Among the others who took part in the discussion was Dr. Greene, of Buffalo, a delegate from the Fourth District Branch Association, who spoke in terms of the highest recommendation of the local use of a solution of persulphate of iron, applied in the form of a spray, in addition to appropriate constitutional measures.

DR. R. C. VAN WYCK, of Hopewell Junction, Dutchess County, read a paper on the

#### TREATMENT OF CEREBRAL HÆMORRHAGE AND EMBOLISM BY THE INTERNAL USE OF CARBONATE OF AMMONIA.

He first gave a detailed history of two cases in his practice illustrating the method of treatment which he had adopted, after which he stated that the advantages which he claimed for it were the following:—

(1) As a diffusible stimulant to the general circulation, relieving the anemia which is present in the brain, increasing the cutaneous circulation, and inducing perspiration, in this way relieving intracranial pressure.

(2) By its direct action in dissolving the clot. The only agents which possess this property are the alkalies, and the most efficient of these is ammonia.

(3) In the edema and congestion of the lungs so often seen in apoplexy the use of this salt will frequently relieve the condition, partly by its stimulating action on the terminal capillaries, and also by its expectorant action on the bronchial mucous membrane.

(4) By keeping up the alkalinity of the blood and preventing further thrombosis.

He said that he did not claim for this drug a specific action, but only that it was of service as an efficient auxiliary to the use of other measures. The following he suggested as the proper order of treatment in cases of cerebral hemorrhage:—

(1) To endeavor to control the prodromal symptoms, which threaten an attack of apoplexy, by prompt venesection and catharsis.

(2) To relieve the period of reaction after paralysis has taken place by arterial sedatives, preferably aconite.

(3) To remove the exudation, relieve cerebral anæmia and pulmonary congestion, and prevent further thrombosis by the use of carbonate of ammonia.

(4) To support the system by nourishing, but unstimulating diet, and by remedies which specially nourish the brain tissue, such as lacto-phosphate of lime, cod-liver oil, and phosphide of zinc.

(5) To increase the muscular development by massage, frictions, electricity, and strychnia.

The carbonate of ammonia, he said, should never be given in cerebral hæmorrhage until the period of reaction had fully set in, say in from ten days to two weeks. It should then be given continuously for at least a month, or until the retrograde changes in the clot were accomplished. In thrombosis and embolism, if the diagnosis could be clearly made, it was to be given at once. The doses employed by him was five grains, three or four times a day, and it was given in half an ounce of liquor ammoniac acetatis. He said there was one class of cases of cerebral hæmorrhage in which the carbonate of ammonia had not acted well in his hands, namely, when the condition was associated with interstitial nephritis and hepatitis. Here he had had good results from the use of sodium phosphate, in doses of from twenty to thirty grains, given, in the infusion of dandelion, three times a day after meals, and of bichloride of mercury in doses of one twenty-fourth of a grain, given (sometimes combined in a pill with digitalis and squill) before meals. At the end of the paper Dr. Van Wyck read a letter from Prof. Roberts Bartholow in regard to the utility of the carbonate-of-ammonia plan of treatment, in which he stated that there was a class of cases in which he had seen the most admirable results, namely, cases of thrombosis of cerebral vessels due to chronic arteritis. Embolism of the brain secondary to lesions of the cardiac valves, he said, was another condition in which the same treatment was very effective.

Dr. C. S. Wood, of New York, read the

REPORT OF A CASE OF METASTASIS OF ACUTE RHEUMATISM FROM THE SHOULDER AND ARM TO THE MENINGES OF THE BRAIN, RESULTING FATALY.

The rheumatic attack referred to was in a patient thirty-eight years of age, who had inherited a strong rheumatic tendency, and was treated first with salicylate of soda, and afterward with alkalies in full doses, morphia being also administered from time to time, as occasion required. Eight days from the commencement of the illness the metastasis took place, and the fatal result rapidly ensued. Toward the last the temperature went steadily up, until it finally reached 106° F. It was impossible to obtain an autopsy in the case. Dr. Wood said that in his professional career he had met with a number of similar cases, though the most of them occurred while he was serving as a surgeon in the army. In conclusion, he quoted the opinions of various standard authorities upon this subject.

The last paper was read by Dr. J. G. PORTEOUS, of Poughkeepsie, and was on

HYPERTROPHY OF THE PROSTATE GLAND.

Personally, he said, he had had but little experience except with the senile variety of the trouble,

which was by far the most common. The administration of drugs had no effect in reducing the size of the enlarged prostate, and he believed that the best treatment was the early use of the soft catheter, which should be passed at least once in every three or four days. By this means it was possible to avert or greatly postpone the distressing symptoms so often met with in this condition; but if a case were left too long without treatment there would almost inevitably be great difficulty in its management. There was one important lesson which he had learned in connection with this affection, and that was the great danger of completely emptying the bladder. Formerly he used to do this, but the results had more than once been so disastrous that for a long time he had employed the plan of gradual evacuation. When this was practised there was seldom any blood, and the quantity of pus was much less, while the patient lived longer, and got along with less suffering than he would otherwise. When there was very great irritation present it was advisable to resort to the aspirator until this had been sufficiently allayed to permit the use of the catheter. While this was not necessary in ordinary cases, he believed that the aspirator would in the future be more often used in connection with hypertrophied prostate than it was at present.

Dr. J. W. S. GUTLEY said that the idea of gradual evacuation of the bladder in these cases had been first suggested by Sir Benjamin Brodie, and Dr. Porteous, by careful observation, had arrived at the same conclusions as that great master. Young practitioners are always anxious to see the last drop of urine, and he said he could relate a dozen cases that he knew of in which death had resulted from the complete emptying of the bladder. Caution in this regard was, then, the principal practical point that was impressed in the paper of Dr. Porteous. Another point to which he should like to call attention was the existence of incontinence of urine in connection with enlarged prostate. Hypertrophy of the prostate was not a single entity, but consisted of a number of entities. At the present day we could determine what form of hypertrophy was present, and this knowledge guided us in the selection of the proper instrument to be used. He said he agreed with the author of the paper that, as a rule, the vulcanized rubber catheter was the best, particularly for patients to pass themselves; but cases were met with from time to time in which it was not possible to enter the bladder with it, namely, those with intra-urethral hypertrophy, with a zigzag course of the urethra, and perhaps a bar at the neck of the bladder. Here the metallic flexible elbow catheter of Mercier was required.

When there was a false route, Mercier's invaginated catheter was invaluable. With this instrument Dr. Gutley said he had never failed to get into the bladder, and since he had been in possession of it he had entirely discarded the use of the aspirator. Every man who had enlarged prostate, he went on to say, did not have retention. On the contrary, the patient might have incontinence, which was not to be confounded with the dripping of an overflowing bladder. He next spoke of the importance of the surgeon's being on his guard against the possible stoppage of the orifice of the catheter

by a blood clot, and, finally, he condemned the use of cocaine, which was recommended by Dr. Newman in painful cases. It was highly desirable, he thought, that the surgeon should have the sensations of the patient to guide him, — otherwise there was danger of making a false passage, — and the skilful catheterist, having made a careful diagnosis and selected the proper instrument, would not be at all likely to give pain.

### Recent Literature.

*The Invalid's Tea Tray.* By SUSAN ANNA BROWN. Author of *Forty Puddings*. Boston: James R. Osgood & Co. 1885. Pp. 67.

When the doctor is asked what *shall* we give our invalid to eat he is often at his wit's ends to supplement the efforts which have been already made by the nurse and family. This little book contains suggestions which will make many an anxious watcher bless the author for her thoughtfulness, and will relieve the doctor from the puzzling question. The book is dedicated to the family physician "whose genial visit in itself combines the best of cordials, tonics, anodynes."

A sort of preface consists of hints which are well worth repeating, if space permitted; though, doubtless, many an individual, who would never carry them into practice, would say: "Why, of course, everybody knows that."

The recipes themselves seem praiseworthy, but we prefer the formula for limewater of the U. S. Pharmacopœia to that of the "Tea Tray." The latter directs that it shall stand over night to settle, but does not refer to the effects of long exposure of limewater to air laden with the products of respiration.

*The Refraction of the Eye. A Manual for Students.*

By Gustavus Hartridge, F.R.C.S. With eighty-seven illustrations. 12mo. London: J. & A. Churchill. 1884. Pp. 199.

We have read this little book with interest. It seems adapted to be of very considerable advantage to the student in the study of the principal facts regarding the refraction of the eye and the means of determining and correcting its errors. Facility in accurate estimation of errors of refraction can, as the author justly observes, only be acquired by the practical working out of a large number of cases, and, we may add, by a more thorough study of the theory than the scope of the manual affords. As an introduction it will prove of much value. The first chapter (fifteen pages) is given to the statement of certain elementary principles of optics. Only great haste or carelessness can account for the statement made on page 5 under the head of "Reflection from convex mirrors": "The principal and conjugate foci are always on the same side of the mirror as the luminous point, while the visual focus is always on the other side of the mirror," in direct contradiction as it is to sentences immediately preceding. At the beginning of the next chapter we are surprised to learn that "the refracting system of the eye is so

beautifully arranged that but little, if any, spherical or chromatic aberration takes place, as is the case with ordinary optical instruments." But these examples are by no means to be taken as a sample of the whole. There are occasional inaccuracies or looseness of expression which we shall hope to see corrected in another edition, and we should have been glad to find a more accurate definition of presbyopia, a term which, in our experience, is not always exactly comprehended by the student. According to the definition given on page 22 and repeated on page 148, "When the near point has receded beyond beyond two centimeters (which usually occurs in the emmetropic eye about the age of forty-five), the eye is said to be presbyopic," — a hypermetrope of high degree might be said to be presbyopic before he was out of his teens. The merits of the book, however, far outweigh its defects. The chapter on retinoscopy appears to us the best, and to have excited the warmest interest of the author. Mr. Hartridge, in common with several younger English ophthalmologists, has a preference for this method of measuring errors of refraction. In our opinion it is not, even on the showing of its advocates, equal to the direct examination with the ophthalmoscope, although it is probable that by many skill in its employment is more easily acquired. We commend the book to our readers.

*A Guide to the Diseases of Children.* By JAMES FREDERICK GOODBART, M.D., F.R.C.P., Assistant Physician to Guy's Hospital, and Lecturer on Pathology in its Medical School; Physician to the Erienna Hospital for Sick Children. Revised and edited by LOUIS STARR, M.D., Clinical Professor of Diseases of Children in the Hospital of the University of Pennsylvania; Physician to the Children's Hospital, Philadelphia. With Formulae. Philadelphia: P. Blakiston, Son & Co. 1885.

This work is written in a very agreeable style, carrying weight from its simplicity and clearness and the evidently large and matured experience of the author. It is especially adapted to the needs of the practising physician rather than for the medical student, as with rare discernment it takes up important points in the details of the disease and deals with them practically, leaving the general typical course of the case to the other numerous writers who have already covered the ground in this class of cases.

The type and paper are especially to be commended, and the editor, Dr. Starr, can be said to have offered a very attractive book to the medical profession.

— Dr. Sturge, a medical missionary to Siam, relates how a native doctor administered an emetic to a lovesick lady who had swallowed a quantity of opium with suicidal intent. The scientist of Siam took a live eel, clipped off a part of his tail to make him squirm in a lively manner, and then pushed him, tail first, down the romantic damsel's throat. When the eel returned to the stream of running water, near which the girl was made to recline, the opium quickly followed him.

283 WASHINGTON STREET, BOSTON, MASS.

## METAPHYSICS AND MIND-HEALING.

THE belief in the antithesis of subject and object and the reality of matter is the very earliest and firmest of human beliefs, as has been recently shown by McCosh in his philosophical essays; nowhere, however, more clearly than by Herbert Spencer in the second volume of his "Principles of Psychology." The latter, replying to the metaphysical postulate, "that we are primarily conscious only of our sensations; that we certainly know that we have these, and that if there be anything beyond these, serving as a cause for them, it can be known only as an inference from them," an argument stated with great force by Berkeley, and which has more or less swayed the acutest thinkers (including both Mills) since Berkeley's time—demonstrates that the thing primarily known "is not that a sensation has been experienced, but that there exists an outer object." Instead of admitting that the primordial and unquestionable knowledge is the existence of a sensation, he makes it plain that "the existence of a sensation is an hypothesis that cannot be framed until external existence is known." This is proved, first, by the argument of priority, *realism* being, in the history of the race as well as in the history of every mind, the primary conception, without which it is not possible even to frame the idealistic conception; second, by the argument from simplicity, the mental process which yields realism being simple and direct, while the idealistic or sceptical belief is an inference from a long-involved and indirect train of reasoning; third, by the argument from distinctness, the realistic belief being founded on deliverances of consciousness given in the vivid terms we call sensations, "which excite a confidence immeasurably exceeding the confidence excited by deliverances given in the faint terms we distinguish as ideas." In short, the realistic philosophy is shown to have the sanction of commonsense and of consciousness, "which is to be presumed trustworthy until proved mendacious."

The great work of Bishop Berkeley, which first affirmed in intelligible language the proposition that

matter is unreal, being on rigid analysis resolvable into "sensations of the percipient mind," appeared in 1710. There was nothing so very bad about it, considered as a whole, and as a piece of clever thinking. Berkeley's reasoning was directed against the materialists and atheists, and he believed that he had dealt the deathblow to the systems of philosophy represented by these names. If there be no external world, he argued, the phenomena of sense can be explained only by supposing a Deity in whose mind exists all that we refer to objective existence, and who necessitates perception in us. It is doubtful if Berkeley ever made a convert from the false belief against which his philosophy was aimed; at least, however, to his credit be it said, he never undertook to overturn men's faiths in the practical realities of life. He did not venture into the domain of medicine, except to proclaim his unquestioning faith in the virtues of his panacea—*tar water*! He never asserted disbelief in the reality of disease, and in this and all other respects his actions were based on principles which his philosophy denied.

It is one of the singular phenomena of our day that Berkeleyism should have been made the basis of a system of *therapeutics* (?) which dignifies itself with the name of *science* and imposes itself on hosts of the unwary and gullible. According to this system "body" is unreal, and disease is unreal, and "mind" is the only reality and is potent over all ailments, which are only incidents of false beliefs.

The true way to get well is resolutely to disbelieve that you are sick, and to act accordingly.

"Our Monday Lectureship" received a notable reinforcement when lately the leading exponent of the new evangel of mind *vs.* matter was in solemn state ushered upon the platform "consecrated to the investigation and elucidation of the deepest questions of science, philosophy, and religion," and given an opportunity to instruct "the most cultured of New England audiences" in the mysteries of metaphysical moonshine.

A correspondent who prefaces his demand by the undeniable proposition that "the ignorance and credulity of this nineteenth century are most disheartening and appalling" asks us to review a certain "textbook" of metaphysical "meditation." We beg to be excused—life is too short; a page or two would be too much of a task! We content ourselves with presenting our correspondent's opinion, which certainly sounds like those primary dicta of consciousness "one cannot suppress without mental suicide," and which we therefore shall not dispute: that "the system is the wildest chimera that ever entered the human brain, and the exposition most dreamy, dreary, and inconsequential, an insult to commonsense and an outrage on reason."

One striking evil resulting from such misleading teachings is that many excellent, though somewhat weak-minded, credulous, and confiding, people, who

may be suffering from real organic ailments, are induced to follow these professional *ignes fatui* to their own detriment and destruction. Instances of this kind it would not be difficult to find in many New England communities.

#### ANDROLOGISTS: A PLEA FOR MAN.

THE cultivation of the specialties has given rise to a set of terms indicative of the special organs to which the practitioners designated by these terms specially devote themselves. So far as a nomenclature can go these terms are definite enough to have even raised the study of the different organs to the rank of separate sciences. Gynaecologist and gynaecology were two of the earliest of these new terms. Physician, surgeon, and accoucheur were the only divisions known previously in later times though many other terms had been in use at an earlier period. It is somewhat singular that separate names should be so widely applied to practitioners who devote themselves to the diseases of women, while the gentlemen whose practice lies wholly among their own sex should still be without a name. Every city of any size contains men who are almost exclusively devoted to the diseases of the male sex, but as yet they are without a name.

We are far from desiring to add unnecessarily to the fast-increasing number of new terms in the profession, but the name at the head of this article would seem to be a proper one, if such a name were needed. We call attention to it rather to express our wonder that it has never been used than to suggest its adoption. Genito-urinary diseases covers well enough the class of work, but the practitioners themselves can only be designated, without such a term, as gentlemen devoted to genito-urinary diseases. In these days, when the elevation of woman occupies so great a share of the attention of mankind, a feeble claim for the rights of man to an equal place with woman in medical nomenclature may not be entirely out of place.

#### THE AMOUNT OF ALBUMINOIDS IN HUMAN MILK.

At a late meeting of the College of Physicians of Philadelphia, Drs. A. R. Leeds and A. V. Meigs discussed at length the relative merits, or rather the demerits, of their respective methods of milk analysis, and especially the correctness of their results in regard to the percentage of albuminoids contained in human milk.

Dr. Leeds claimed that by his method he, as the result of the analysis of eighty samples of human milk, showed the average amount to be 1.99 per cent. of albuminoids, the range being from 0.85 to 1.86 per cent., while Dr. Meigs claimed that by his

method forty-three samples showed an average of 1.016 per cent., having already stated in a published paper, to which he referred, that it never contained more than 0.70 to 1.50 per cent. In this same paper Dr. Meigs claims for his method many advantages, especially mentioning rapid determinations, and says that a full analysis takes from three to five days, while if the casein and sugar are not separated it can be done in from three to four hours. These, however, are the two factors which he seems to consider of the greatest importance.

The method advocated by each of these gentlemen is much more complicated than that employed by the late milk inspector of this city, and they each showed good valid objections to the method of the other. Such a proximate analysis as Dr. Meigs's would take three to four hours to arrive at results which the inspector, in his late milk report to the city of Boston, shows may be reached in about as many minutes. The same method permits some twenty full analyses in a single day, whilst Dr. Meigs's method would require three to five days to complete a single one. The other method advocated by Dr. Leeds is a modification of the so-called Ritthansen's. When this last was proposed at a late meeting of the American Society of Public Analysts for their general adoption, as the official method, it obtained but little support, being generally considered so complicated as to easily admit of grave errors. As far as the different results obtained by the two methods for the percentage of albuminoids present in human milk are concerned, those of Dr. Leeds would generally be accepted as the more accurate.

#### MEDICAL NOTES.

—We are quite accustomed to seeing the names of our medical countrymen, so many of whom are quoted in the French and German journals, masquerading in strange orthographical habiliments. Scarcely one among them

"But doth suffer a sea change  
Into something rich and strange."

But for richness and strangeness, few metamorphoses equal that performed by the *Lyon Médicale* upon the name of an eminent English writer, who but for the Christian name would have fallen quite into oblivion as *Milner Sakerjell*.

—Attention has lately been called to an injurious effect produced upon men by the handling of dynamite (independently, be it said, of the injurious effect produced by the explosion of the dynamite). It is manifested by headache, tinnitus, and palpitation. One recent writer believes it to be due to small amounts of nitroglycerin swallowed, saying that a man who had formerly had the habit of tasting his fingers to see if the dynamite was washed off recovered from his symptoms on discontinuing his habit and wearing gloves. Others claim that the

"dynamite headache" is due to inhalation, and is similar to that caused by nitrite of amyl; that it is inseparable from the use of the explosive, at least until immunity is caused by either prolonged use or idiosyncrasy.

—In consequence of the increase of shortsightedness, and the theories current as to its cause, a new departure in book-printing has been made in Holland, the letters being printed in dark blue on a pale-green page. Messrs. Issleib, of Berlin, have also printed one of their latest publications, "Die naturgeschichte der Berlinerin," in this manner, but the result, as we learn from *Science*, is not wholly satisfactory.

—The penny-dinner movement in England has run against a snag, which snag, as might be expected, is the difficulty on the part of the would-be partakers of securing the requisite penny. The difficulty is sought to be met in two ways: first, by the establishment of halfpenny-dinners, of which eight dépôts are now in operation. This device is threatened with the same danger that has overtaken its more ambitious predecessor. For in the most hopeless slums of London and Birmingham, where hundreds of unnamed and unclaimed children roam the streets with no other dependence than what they can pick up, how is it to be much easier to pick up two farthings than four? The second measure suggested is to disburse to the proletariat the tickets, that is, the pennies, to pay for the dinner, and here the line between the new *quid pro quo* system and the old-fashioned, downright pauperization becomes too fine for the unpractised eye to follow it.

—Mr. Berkeley Hill, in the *British Medical Journal*, January 1885, page 226, expresses his agreement with the writer of an article in the *Journal*, November 8, 1884, in stating that circumcision is rarely necessary for simple phimosis; but thinks that he has assumed too hastily that surgeons overlook the facility with which expansion of the free border may be obtained. Mr. Hill uses the prepucial dilator, invented by Mr. Carver, of Cambridge, and finds it to answer perfectly well. The author further states that he generally applies the dilator for the first time, and allows the patient to do it himself afterward. Few cases require more than six or eight applications to widen the narrow free border to the necessary extent. If the two blades of the dilator be slowly screwed apart, the skin is not split, and the operation is painless.

#### NEW YORK.

—A number of cases of typhus fever have been reported during the last week or two in different parts of the city. Six of them were in two tenement-houses in Mott Street, not far from the quarters of the Board of Health, the origin of which does not seem as yet to have been satisfactorily traced.

—The new Carnegie Laboratory, with all its admirable appointments, was thrown open to the inspection of the profession on the evening of May 14th, when the Koch culture-apparatus, together with the different varieties of bacillus cultures and a number of interesting pathological specimens, were exhibited by Professors Janeway and Dennis and their assistants.

—The second annual report of the New York Skin and Cancer Hospital shows that 1,010 new out-patients had been treated, and sixty-two have occupied beds in the Skin Department during the past year. In the Cancer Department 100 patients have been treated and fifty-five operations performed. Besides the building in East 34th Street the institution has a country branch at Fordham Heights.

—Dr. Alexander B. Mott has been appointed consulting surgeon to Charity Hospital, and Dr. Charles E. Simmons one of the Commissioners of Charities and Correction.

—The *Rochester Union* tells of a physician in that city who has, among the poorer families under his care, one wherein an infant has been left to the care of a tender and affectionate father, the mother having been taken to an insane asylum. On a recent visit the doctor inquired how the child was getting along, and what food he was giving it. "First-rate," replied the paternal nurse; "I buy impaired food and condemned milk for the baby, and it thrives well upon them."

—The cornerstone of the new Manhattan Hospital, at 131st Street and 10th Avenue, was laid May 23d. The hospital is being built by the Manhattan Dispensary Association, which has maintained a free dispensary in Harlem since 1862, but has never as yet had a hospital under its charge. The lot purchased by it is 130 feet square, and the building now in course of erection will be forty by forty-five, and will constitute one wing of the hospital as finally completed. It will be ready for occupancy by the first of October next. Among those who made addresses on this occasion was Dr. L. A. Rodenstein.

#### PHILADELPHIA.

—The State Medical Society of Pennsylvania held its thirty-sixth annual session at Scranton, May 27th, 28th, and 29th.

—The University of Pennsylvania and the Jefferson College have each discontinued their Post-Graduate course.

—The Pennsylvania Legislature on Tuesday last, May 19th, finally passed the *State Board of Health Bill*, which only awaits the signature of the Governor. The State Medical Society passed resolutions in favor of a State Board of Examiners independent of the Colleges.

## Correspondence.

## A USEFUL FORM OF LIGATURE.

LOWELL, 15 First Street, April 20, 1885.

*Mr. Editor.*—I enclose a drawing which illustrates a method of ligation. It has been suggested to me that it might be useful in ligating the broad ligament in ovariectomy. I have found it valuable, though not in that operation.

An ordinary double thread with a single needle is passed loosely back and forth through the whole extent of the part to be ligated. Each alternate loop of each thread is then cut. This leaves a loop and two free ends for each section. (The ends to be tied have corresponding numbers in the drawings.) The ends being then tied the ligation is completed.

This is very quickly done, and in certain cases seems to be expedient and successful.

By coloring one of the threads (that is, the thread on one side of the needle) an obvious advantage will be gained; the danger of confusion in hastily taking up the alternate threads will be avoided. The substance used should not, of course, weaken the thread or poison the tissues. For this purpose iron tannate is suggested.

WM. H. LATROP.

## PARIS LETTER.—MEDICAL MATTERS IN PARIS.)

[FROM OUR SPECIAL CORRESPONDENT.]

PARIS, May 12, 1885.

*Mr. Editor.*—For didactic and experimental courses the students meet in the old *Ecole de Médecine*. There are two amphitheatres ("the large" and "the small"), the former being used for general, the latter for special, courses. The larger one was described in my letter on the Congress of French Surgeons. It is lighted wholly from above, a good arrangement for both lecturer and students. The manner of giving lectures with black-board, plates, etc. is much the same as with us.

Vulpian gives a most interesting course, during the spring *semestre*, on brain irritation, illustrating his subjects largely with dogs, rabbits, and frogs. It was very striking to see a rabbit thrown into an epileptic convulsion by a subcutaneous injection of absinthe. Probably a moral lesson to certain of the audience.

Vulpian, with rough sandy hair and beard, and seedy dress, looks rather like one of our country clergymen than a Parisian *savant* of brilliant reputation. His utterance is rapid and indistinct, but he attracts a large class. Of course, his statements and statistics are impressive and he receives eager attention. He is followed by Damascchino, decidedly his opposite in look and manner,—a bright, quick, eloquent young man of small stature. His subject is the nervous system and its diseases. He illustrates constantly and very beautifully by means of a stereopticon, the room being darkened and the pictures thrown upon a white curtain drawn down behind him. He thus shows microscopic preparations of brain, spinal cord, nerve-cells, and nerves,

in normal and pathological conditions, exquisitely mounted; likewise photographs of patients who naturally thus became of life size. This use of photographs is a very clever idea. The attitudes and expressions resulting from various nervous affections were exhibited in a very intelligible manner. Probably a student would more quickly detect abnormalities of this nature in a large picture than in the patient himself.

Damascchino's is one of the most interesting of the didactic courses. Tarnier lectures here on obstetrics. Of course, a strong man in this department. By the by, Lusk's book on obstetrics has been translated into French, and was presented the other day at the *Académie de Médecine*, in translation, with warm encomium.

Brouardel holds a course on matters connected with legal medicine: death by drowning, asphyxia, infanticide, and the like. An accomplished lecturer and a man of influence. He it is who makes the autopsies in criminal cases of note. In the journals one constantly sees his name in connection with violent deaths. He is professor at the morgue, of which more shortly. In the smaller amphitheatre are given lectures on special topics: fractures, orthopaedy, gynaecology, throat and chest affections, etc. Clinical medicine, surgery, and practical midwifery are confined to the hospitals, where, in the amphitheatre of each, as already remarked in a former letter, the principles of these branches are expounded after the morning visit; so that the didactic course at the school rarely begins before noon, the hospital visits commencing at 8 or 9 A. M., according to the hospital.

Anatomy and physiology are taught in the Paris school with thoroughness and care. There are many minor courses, including practical laboratory work of every description. The students impress one as being much in earnest. They are soberly attentive, take copious notes, and their general bearing is very respectful. Excitable on occasions they are, it is true, as all history of *émulés* in Paris clearly indicates, but when at work they are in earnest. Their average age is perhaps five years beyond that of our students in medicine. Most of them are bearded and nearly all wear the regulation silk hat. They are good readers too. The library of the *Ecole de Médecine* contains 100,000 volumes and receives two or three score of medical journals, French, German, English, and Italian. I found only one American publication—Mundé's *Journal of Obstetrics*. The room is very capacious and is open from eleven to five during the day, seven to ten in the evening. There are two-faced reading-desks, a dozen or more, which extend across the room. Usually nearly every chair is occupied by men—women as well—who are reading or taking notes. What this free access to unlimited books and journals is to the student need not be made more apparent. Even a stranger may read and study here without question.

Opening from the same floor is the celebrated Orfila Museum, which contains thousands of exquisite and classified anatomical preparations of every possible nature. You may study here the entire structure of both human beings and animals from the first week of fetal life to maturity. Near by, but in another building, is the superb Dupuytren collection, in which pathological anatomy, skin and syphilitic diseases may be studied, and where also are beautiful and numerous wet and dry normal anatomical preparations.

Women are constantly met at lectures. I have seen seven in one audience. They do not appear to attract any attention, take notes exceptionally, but are good listeners. I never saw one at a medical or surgical clinic, but they attend the obstetric courses very faithfully. Meeting women thus day after day one naturally becomes accustomed to their presence among male students, but the queerness of it cannot be argued out of existence, especially when one meets a woman at an autopsy. Of this, more in another place.

The new and handsome medical school building of white sandstone, in process of erection in the *Rue de l'École de Médecine*, and immediately opposite the old structure, grows apace, but apparently will require another year for completion. It will be very well lighted and far superior to the old building. The same horde of new and second-hand medical book-shops cluster about, and the familiar signs of makers of surgical instruments and orthopedic appliances are still to the fore. It is curious to observe how many French medical pens gravitate to diseases of the organs of generation, to prostitution, *et id genus omne*, quite needlessly, one would think. In the windows even of the first-class bookshops here is a proportion of these productions which in England or at home would have an absurdly quackish look. This, however, quite tallies with the photograph and picture-shops in the Rue Rivoli and elsewhere, nor forgetting the Salon. Even under the Empire, never was there such a mawkish display of female anatomy undraped and in such impossible postures.

The people of Paris have had a hard time during the

past winter, for the city has been nearly empty of visitors, but they make light of cholera, and I did not meet a native who failed to pool-pool at the epidemic and any fear of its recurrence. The feeling that "respectable people cannot have cholera" is very strong in Paris. The quality of the material which suffered in the late epidemic largely bears out the truth of this axiom. Moreover, many believe that the number of cases of actual cholera was far smaller than was reported. This endeavor to belittle the epidemic naturally brings to mind the fact that "Paris lives on strangers," and at present strangers in general do not allow themselves to remain long in the city. There is an undercurrent of belief that cholera will reappear by-and-by, and if it be a mistake to leave Paris before warm weather appears, it is the proper kind of mistake, namely, upon the safe side. There is no evidence that the authorities are especially forearmed against reappearance of the disease, and when I said to a physician with whom I spoke of the condition of the dirtier hospitals: "And cholera?" he shrugged his shoulders and made no other reply.

## REPORTED MORTALITY FOR THE WEEK ENDING MAY 23, 1885.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 2,400; under five years of age 807; principal infectious diseases (smallpox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhoeal diseases) 392, lung diseases 361, consumption, diphtheria and croup 100, diarrhoeal diseases 65, scarlet fever 61, measles 43, malarial fevers 38, typhoid fever 22, whooping-cough 23, erysipelas 15, cerebro-spinal meningitis 14, purpural fever 10, smallpox one. From measles, New York and Brooklyn 13 each, Philadelphia and Boston six each, St. Louis and Cambridge two each, District of Columbia one. From malarial fevers, New York 12, Brooklyn and St. Louis six each, Baltimore and — five each,

Philadelphia two, District of Columbia and Charleston one each. From whooping-cough, New York nine, Philadelphia five, Brooklyn and Baltimore two each, St. Louis, District of Columbia, Nashville, Lawrence and Lynn one each. From erysipelas, Philadelphia six, New York five, Brooklyn two, New Orleans and Fall River one each. From cerebro-spinal meningitis, New York four, Philadelphia and Baltimore two each, St. Louis, New Orleans, New Haven, Charleston, Lowell, and Fall River one each. From purpural fever, New York four, Boston and St. Louis two each, Philadelphia and Fitchburg one each.

One case of smallpox was reported in St. Louis. Measles 92, scarlet fever 44, diphtheria and croup 22, typhoid fever three, in Boston.

In 115 cities and towns of Massachusetts, with an estimated population of 1,432,125 (estimated population of the State 1,455,104), the total death-rate for the week was 18.19, against 17.52 and 17.93 for the two preceding weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,906,446, for the week ending May 9th, the death-rate was 20.2. Deaths reported 3,440: infants under one year of age 722; acute diseases of the respiratory organs (London) 287, measles 181, whooping-cough 116, fever 37, scarlet fever 36, diphtheria 33, diarrhoea 30, smallpox (Liv-

erpool and Sunderland one each, Manchester two, London 44) 48. The death-rates ranged from 14.1 in Brighton to 36.8 in Newcastle-on-Tyne; Birmingham 19.4; Bradford 19.0; Hull 17.9; Leeds 20.4; Leicester 15.3; Liverpool 23.4; London 18.7; Manchester 26.0; Nottingham 18.0; Sheffield 19.5. In Edinburgh 18.1; Glasgow 24.1; Dublin 28.5.

For the week ending May 9th in the Swiss towns there were 46 deaths from consumption, diarrhoeal diseases 22, lung diseases 19, diphtheria and croup six, smallpox and measles each five, purpural fever four, whooping-cough two, erysipelas one.

The death-rates were: at Geneva 16.2; Zurich 13.6; Basle 15.9; Berne 26.2.

The meteorological record for the week ending May 13th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending	Barom-eter.	Thermometer.			Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.
	Daily Mean.	Daily Mean.	Maximum.	Minimum.	7.23 A. M.	3.23 P. M.	11.23 P. M.	7.23 A. M.	3.23 P. M.	11.23 P. M.	7.23 A. M.	3.23 P. M.	11.23 P. M.	7.23 A. M.	3.23 P. M.	11.23 P. M.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MAY 23, 1885, TO MAY 29, 1885.

BRECHMIN, LOUIS, captain and assistant surgeon. Ordered for temporary duty at Fort Omaha, Neb. S. O. 44, Department of the Platte, May 18, 1885.

BROWN, JESSE M., major and surgeon. From Department of the East to Department of the Platte.

DEWITT, CALVIN, captain and assistant surgeon. Ordered to Department of the East. S. O. 105, A. G. O., May 8, 1885.

COLESON, JOSEPH K., captain and assistant surgeon. Leave of absence extended ten days. S. O. 109, A. G. O., May 13, 1885.

DELOFFRE, A. A., captain and assistant surgeon. Assigned to duty at Fort Sisson, D. T. S. O. 46, Department of Dakota, May 1, 1885.

KANE, JOHN J., captain and assistant surgeon. Leave of absence for seven days extended one month. S. O. 109, A. G. O., May 13, 1885.

CARTEL, E. C., first lieutenant and assistant surgeon. Leave of absence extended one month. S. O. 106, A. G. O., May 9, 1885.

HARRIS, ALBERT, major and surgeon. Ordered from Department of Missouri to Department of the East.

BROWN, H. E., major and surgeon. Ordered from Department of the East to Department of Missouri. S. O. 121, A. G. O., May 27, 1885.

DEWITT, CALVIN, captain and assistant surgeon. Ordered for duty at Newport Barracks, Ky. S. O. 107, Department of the East, May 22, 1885.

HALL, WILLIAM R., captain and assistant surgeon (David's Island, New York Harbor). Ordered for temporary duty at "Willet's Point, N. Y., during absence of post surgeon. S. O. 121, A. G. O., May 27, 1885.

SPENCER, WILLIAM G., captain and assistant surgeon. Ordered for duty at Fort Sisson, D. T. S. O. 55, Department of Dakota, May 20, 1885.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE WEEK ENDED MAY 16, 1885.

LEESBERRY, C. S. D., surgeon. Granted leave of absence for thirty days. May 12, 1885.

GOLDSBOROUGH, C. B., passed assistant surgeon. To proceed to Mass Point, Miss., for special duty. May 16, 1885.

#### SOCIETY NOTICES.

SUFFOLK DISTRICT MEDICAL SOCIETY.—The *Section for Clinical Medicine, Pathology, and Hygiene* will meet in the Hall of the Harvard Medical School, on Tuesday, June 9th, at 8 o'clock. Papers: Dr. W. N. Bullard, of Boston, "A Case of Progressive Muscular Atrophy," with presentation of the patient. Dr. W. Everett Smith, of Framingham, "Hereditary Ataxia, with six new cases"; Microscopic Demonstration of Spinal Cord and exhibition of patient. Dr. E. C. Seguin, of New York, Drs. S. G. Webster, G. F. Jelly, J. J. Putnam, C. F. Folsom, J. H. Denny, H. P. Quincy, and others are expected to take part in the discussions. Members of the profession are cordially invited to attend.

ALBERT N. BLODGETT, Secretary.

GYNECOLOGICAL SOCIETY OF BOSTON.—The next regular meeting of the Society will be held at 19 Boylston Place, June 11th, at 4 o'clock P.M. The paper of the meeting will be, "A Report of Twelve Successful Cases of Ovariotomy," by Dr. L. S. Fox, of Lowell, Mass.

H. J. HARRIMAN, M.D., Secretary.

ANNUAL MEETING OF THE RHODE ISLAND MEDICAL SOCIETY.—The seventy-fourth annual meeting of the Rhode Island Medical Society will be held in Lyceum Hall, 62 Westminster Street, Providence, at 10 o'clock A.M., on Thursday, June 11, 1885. The Annual Address will be delivered by the President, Oliver C. Wiggins, M.D., at 1 o'clock P.M. Subject: "The Nature of Original Inquiry." The annual dinner in Blackstone Hall, Washington Street, at 2 o'clock P.M. Dr. Eugene Kingman, Anniversary Chairman. Candidates for admission to the Society are requested to meet the Board of Censors in the Medical Library, 51 North Main Street, Providence, at 10 o'clock A.M., on Tuesday, June 9th.

G. D. HENSEY, M.D., Recording Secretary.

ANNUAL MEETING OF THE NEW HAMPSHIRE MEDICAL SOCIETY.—The ninety-fifth annual meeting will convene in the Opera House, Concord, Tuesday, June 16, 1885, at 11 o'clock A.M. Annual Address by the President, John Wheeler, M.D., of Pittsburg. The annual dinner will be served Tuesday, at the Phenix Hotel, at 2 P.M. Tickets will be for sale by the Committee of Arrangements at the opening of the morning session. The Anniversary Chairman will preside.

G. P. CONN, M.D., Secretary, Concord, N. H.

MAINE MEDICAL ASSOCIATION.—The thirty-third annual meeting will be held in Common Council Chamber, City Building, Portland, Me., Tuesday, Wednesday, and Thursday, June 9, 10, and 11, 1885.

CHAS. D. SMITH, M.D., Secretary.

## Lecture.

## ANTISEPTIC SURGERY.

THE ANNUAL DISCOURSE BEFORE THE MASSACHUSETTS MEDICAL SOCIETY, JUNE 10, 1885.

BY FRANKLIN K. PADDOCK, M.D., OF PITTSFIELD, MASS.

MR. PRESIDENT AND GENTLEMEN.—From the most remote period in the history of surgery there have been conflicting opinions among eminent surgeons regarding the proper method of treating wounds.

The attention which this subject has for centuries received is indicated by the numerous works that have been written from time to time explaining and describing the various views of many different surgeons.

None of the many plans of treatment recommended proved sufficiently successful in results when thoroughly tested to deserve permanent adoption by the profession.

All concurred in the opinion that the subject was of great importance in the art of surgery, although a satisfactory form of treatment had not been discovered.

There appears to have been no general recognition of the natural tendency of wounds to heal until within a recent period. If this tendency was observed its importance was unappreciated and ignored by the profession who, too often, by treatment, unwittingly retarded a process more essential than any method that could be devised.

I will not trespass upon your patience by asking you to listen to an account of the various treatments which, at different epochs in the history of surgery, have been in vogue, although the subject is far from being devoid of interest and fully demonstrates the natural ability of wounds to heal, even under conditions that would seem to render such a result impossible.

A review of the subject, however, as revealed in the history of wound treatment during the last twenty years, exhibits a greater degree of unanimity of opinion and practice among surgeons than previously existed during a similar period.

Within the two last decades the antiseptic treatment has proved far superior to other methods. Its importance is so generally recognized by the profession at large that it has received, by common consent, the distinctive title of "antiseptic surgery." The principles, merits, and methods of this treatment are more or less elaborately considered in all the recent works on surgery, besides which there are several volumes, each by a different author, devoted entirely to the discussion of the whole subject, including a description of its details and results. The study of its theoretical and practical application is required in the curriculum of all medical colleges of the present day. Since the introduction of the antiseptic treatment there has been signal increase in the success of surgical operations. Many wounds, which formerly were considered almost necessarily fatal, with this method of treatment heal kindly and rapidly. In consequence of this fact a large number of operations are rendered feasible and practicable that were previously undertaken by surgeons only as a last, if not hopeless,

resort. The present high attainment of the surgical art owes so much of its success to the virtues of the antiseptic treatment that its importance should be indelibly impressed upon the mind of every medical man.

There is a certain class in our profession consisting of a very respectable minority who are prone to cling to old ways and customs, and who are disinclined to leave the well-beaten paths that time and long experience have furrowed, although the course may be rugged and difficult and embellished with numerous evidences of unsuccessful results. This worthy class of medical men, forming, as they do, the important rear-guard of our profession, are slow to adopt new theories and modern practices. The merits of this method of treatment however are so great, perhaps I am justified in saying, so exclusively applicable in preference to other forms, that the time has arrived when this Society should exert a decided influence to establish it upon the firm foundation of public opinion. It is certainly far superior to any kind of wound treatment previously practised, and its value has been sufficiently attested to demand, not only a general recognition, but also universal adoption, by the profession. The impression which seems to prevail in certain medical circles that this method is adopted by the entire medical fraternity is incorrect; it is included mainly in the practice of the more prominent surgeons residing in the larger communities of this Commonwealth. But there are a large number of practitioners who are occupied the greater portion of their time in the practice of medicine and are only occasionally called upon to fulfil the duties of a surgeon. Many such, either for want of familiarity with the principles involved in the antiseptic treatment, or because of a lack of a knowledge of the details of the process of applying the dressings, fail to employ this method in their operations or in their management of accidental wounds. So far as I have observed, a similar condition prevails throughout the country.

In Germany the employment of the antiseptic treatment is demanded by public opinion.

A short time since a German surgeon performed an ordinary operation without using modern precautions, and the patient died of septicæmia. Public opinion was sufficiently enlightened, discriminating, and energetic to demand that the operator be prosecuted for malpractice.

A similar sentiment is needed in this country to insure a more general adoption of the antiseptic treatment of wounds, a sentiment like the one which exists regarding the value and the necessity of vaccination.

Were it not for the influence of public opinion Jenner's wonderful discovery would render comparatively very little service to mankind. The public demand the protection afforded by vaccination. So strong and general is this sentiment that the statute renders its neglect an offence incurring the penalty of a fine.

Notwithstanding these facts, there are to-day medical men who, having enjoyed opportunities furnished by education and observation such as to render their opinions upon most subjects valuable, profess to believe that vaccination is injurious rather than beneficial, and, if their views should

prevail, this invaluable boon would be denied the public. The influence of such men would be extremely pernicious and prejudicial to the general health were it not that public opinion is established and their views are discredited.

The principle involved in antiseptic surgery is of as much importance as vaccination, and public opinion must, sooner or later, sustain it with equal vigor.

Although this treatment has been practised twenty years, with results that have earned for it a specific title, still its complete degree of usefulness is not yet attained. Undoubtedly there is a better antiseptic remedy than has yet been discovered. Those already in the service have produced surprising results, which have steadily improved as better methods of application have been gradually developed.

It is not my purpose to proclaim to you the discovery of a new antiseptic agent. Nor have I any original ideas regarding the treatment of wounds to parade before you. I aim simply to present briefly the theory of the antiseptic treatment and its great importance in surgery. The discovery of the cause of putrefaction in wounds led to the development of this method. For years previous to this discovery contact with the air was known to cause, or, more correctly, to be followed by, decomposition of wound secretions. That the air was the cause of this tendency in open wounds to degeneration seemed to be proved by the well-known fact that subcutaneous wounds, exhibiting similar pathological and physiological conditions, healed, not only without putrefaction, but with little or no inclination to suppuration. Whether this effect was occasioned by the chemical or mechanical influence of the atmosphere was undecided. This question, however, was finally settled completely by the experiments of Pasteur. These determined the cause of the decomposition of dead animal tissue, as well as that of wound secretions, to be a substance foreign to, but floating in, the air in the form of a microscopic dust. This invisible material is composed of innumerable germs and spores, termed bacteria and micrococci, whose proportions are so infinitesimal that their detection had eluded the observation of the most careful students of pathology.

Following the announcement of Pasteur's discovery, experiments and investigations were made by Lister, Tyndal, Jeffries, Wyman, and a host of others, which fully demonstrated the harmless influence of pure air upon wounds, and at the same time illustrate the character and functions of putrefactive germs.

The history of these investigations and experiments, revealing, as it does, the pernicious effect of these germs upon the healing process, forms a most interesting and important chapter in the literature of antiseptic surgery, and deserves something more than the brief allusion which I can allow this branch of the topic.

I should do my subject as well as myself an injustice if I failed to allude to the fact that there are still some surgeons who doubt that these germs are the cause of putrefaction. They account for their presence in decomposing animal substances as accidental or, perhaps, as a consequence of finding a

soil in which they thrive. They consider that these organisms feed upon, and help to dispose of, decomposing substances, although they admit that, secondarily, the germs produce a detrimental influence by their excessive development.

Every open wound that is not treated antiseptically exhibits in its secretions, when they are examined with the microscope, certain organisms. These are developed from germs deposited by the air coming in contact with the wound itself or its discharges. These microorganisms vary more or less in form and appearance. The question of the identity of these different-shaped bodies is not yet definitely decided. That one form represents a more perfect development of the other is maintained by some, while the majority believe that they are distinct and separate structures. Their mode of increase is mainly by division. The rapidity of growth depends in a large degree upon the nature of the fluid in which they happen to be. When the conditions are the most favorable for their development they double their numbers once or twice every hour. Under certain circumstances the bacilli increase by the production of spores. The process of their development is almost identical with that of the yeast plant in the alcoholic fermentation. They find in the discharges from a wound every condition, the requisite warmth, moisture, and nutrient material, most favorable for their existence and growth. Planted in this favorable soil they thrive and multiply until every drop of the discharge in every part of the wound is invaded.

The healing process does not seem to be particularly interfered with by the mechanical irritation of these bodies. It is the result of their vital action in appropriating for their growth certain elements contained in the secretions. Decomposition of the organic compounds which constitute the substance of normal discharges naturally attends the functional activity of these organisms. Recombination of the elements thus set free results in the formation of material more or less septic in character and prejudicial to the process of healing.

A similar decomposition of organic compounds, followed by recombination of their elements into new and entirely different forms, characterizes all processes of fermentation. Putrefaction is, therefore, recognized as a kind of fermentation, which, by natural preference, thrives best in animal secretions and devitalized animal tissue.

The course pursued by an open wound during the process of healing is too familiar to need description. These organisms rapidly develop in its discharge. The tissues involved become more or less inflamed. The pus gradually loses its healthy, creamy character and exhibits a fetid odor. The normal secretions are replaced by a septic fluid which bathes its surface and which, to some extent, is absorbed, and impairs the health of the patient. Granulation and healing are rendered slow and tedious. The long-continued, profuse discharge exhausts the system, and the resulting cicatrix is unnecessarily large and unsightly. The introduction of these germs into wounds that are closed while fresh, and coaptation of the parts secured, so as to prevent the accumulation of secretions, is not always, nor perhaps generally, followed by fermen-

tation. The vigor of the healing process existing in the healthy tissues of two opposing surfaces brought into immediate contact is sufficient to destroy the vitality of these organisms.

It is the accumulated or exposed secretions and discharges that furnish conditions favorable for their development. And even these, if composed of normal serum and thick, healthy pus, appear to be able to resist, to a considerable extent, the pernicious influence of the germs, affording them insufficient nourishment to sustain their vitality.

These facts show that, under very favorable circumstances, the presence of organisms in a wound does not necessitate the occurrence of putrefactive fermentation, even when no effort is made by specific treatment to prevent such a result. The ability of wounds to heal, practically without discharge, by the process of scabbing, is a further illustration of this point. Notwithstanding these undoubted evidences of the ability of certain wounds to heal readily without antiseptic treatment, still the tendency of the majority to become the seat of fermentation and decomposition is too frequently demonstrated in practice to question the necessity of some protection.

The demand for some form of treatment that would obviate the detrimental effect of the organisms was apparent soon after the announcement of their discovery. The recognition of this demand, together with the application of measures fulfilling its requirements, by Sir Joseph Lister, twenty years since, is the first legitimate accomplishment in the history of antiseptic surgery. Other surgeons were conscious of the necessity of protecting wounds from germinal influence. Lemaire even used carbolic acid, with fair results, but he evidently failed to grasp a principle, the announcement of which has made Sir Joseph Lister famous.

Since the discovery of the fact that putrefaction can be prevented by the exclusion of germs, it has been determined that after fermentation has been established in a wound, the application of antiseptic agents, remedies which act as germicides, stops fermentation, destroys the organisms, and a normal condition of healing is resumed.

Therefore, in carrying out the principles of antiseptic surgery, one of two objects must be accomplished. Either living germs should be prevented from entering wounds, or accession being allowed they should be removed or destroyed before they have occasioned injury by their development. It is apparent that they can only be deterred from entering wounds that are made by the surgeon during an operation. To attain this it is necessary to saturate the air that is liable to contact with the exposed surface with antiseptic spray. For this purpose, a solution of carbolic acid is usually employed, of the strength of one part of the acid to twenty of water; this is applied with a steam atomizer.

The spray should be used before the first incision is made, and should continue without cessation until the operation is finished and the wound dressed. A thorough saturation of the atmosphere is aimed at without producing excessive moisture.

Every instrument used in the operation should be perfectly clean, and moistened in a solution of the

agent. The hands of both the operator and his assistants should be scrupulously clean and frequently moistened by the same fluid. The sponges should be carefully selected, and, together with the ligatures, sutures, and everything that comes in contact with the exposed surface, should be thoroughly disinfected in order to prevent the admission of vital particles possibly adherent to the articles used in the operation.

All bleeding vessels should be either ligated or their orifices occluded by tension.

The wound should be well sponged, laved, or drenched with a very mild solution of the antiseptic agent before closing it. When the surface is quite large, as is the case in an amputation of a limb or breast, a drainage-tube should be inserted to allow of the escape of any excess of secretions that otherwise might accumulate between the flaps. The latter should be brought into as perfect coaptation as possible by sutures that have been soaked in the germicide liquid.

The next step is the dressing of the wound. This is of no less importance than the other measures and consists in still surrounding the parts with an antiseptic atmosphere. To secure this, loose, porous material is employed for the compresses and bandages, which are thoroughly infiltrated or saturated with the antiseptic agent. Gauze, surgical cotton, jute, oakum, or any other substance that will retain the vapor of the germicide is suitable for protection, provided a sufficient quantity is used in covering and wrapping the parts to entirely absorb the discharge and prevent its coming in contact with the atmosphere at the surface of the dressing. In order to accomplish this the dressings should extend considerably beyond the wound in every direction.

The drainage should especially be provided for by an abundance of absorbent material.

If, at any time during the healing process, the discharge should extend beyond the limit of the dressing, and exhibit indications of putrefaction, the question of re-dressing the wound would need to be considered without delay. If, however, the secretions are not in excess and the proper measures are carried out with the success that almost invariably attends this sort of treatment, the wound practically assumes the condition of a subcutaneous lesion and, like it, tends to recovery without sufficient inflammation to produce suppuration.

The blood-clots, extravasated or effused between the flaps of such a wound, become disintegrated by the growth of cells extending from the tissues. These permeate the clots in every direction, and gradually they are absorbed in the same way that blood is disposed of, that is, extravasated subcutaneously. Wounds, the result of surgical operations, receiving this treatment, rarely require a second dressing in less than seven or eight days, when, as a rule, it will be found that union has taken place and the healing process well established. If catgut ligatures were used then absorption is assured, while non-absorbent ligatures will occupy a small sinus, only of sufficient size to allow their easy removal when separated from their attachment. The disinfected sutures do not cause apparent irritation, although they are permitted to remain longer

than is necessary to induce union by first intention. The employment of a drainage-tube occasions little or no embarrassment to the rapid union of such wounds. Ordinarily they can be removed on the third day.

The dressings should be reapplied and maintained until the openings for the ligatures and drainage are perfectly closed.

The employment of drains composed of substances capable of absorption, like catgut and decalcified bone, simplifies the treatment, as the drains disappear at the end of a few days, when they have performed the duty expected of them.

Union by first intention is the result anticipated in most fresh wounds. This renders the first dressing of greater importance than subsequent ones, for, if the germs can be excluded and inflammation prevented during the first week, the healing is practically completed before the first is removed, and the succeeding treatment consists in the application of very simple dressings. If, however, it should become apparent from the general condition of the patient, the presence of fever, the existence of pain and tenderness locally, and the occurrence of a fetid discharge, that fermentation is established, then primary union should be despaired of and the second dressing applied without delay. The same fidelity should be observed in the application of the second dressing that characterized the first.

The interruption of the fermentative process which has become established in the wound should form an important feature of the subsequent treatment, and test the value of antiseptic agents in destroying the putrefactive organisms.

This leads to the consideration of the second method referred to, of antiseptic treatment. This is precisely the same in all its details as that already described, except that the spray is omitted, and no effort is made to destroy the germs in the air that come in contact with the wound during the operation.

The use of the spray is not absolutely necessary to secure antiseptic results, because of the ease and readiness with which the organisms can be devitalized and removed from the wound surface, after the completion of the operation but previous to the closure of the flaps.

This is accomplished by carefully and thoroughly sponging, lavage, or douching with a solution of the reagent having sufficient strength to destroy the organisms without materially affecting the tissues.

In country practice, especially, the use of the spray, in many instances, is impracticable. A variety of circumstances combine to prevent its employment. Some of these are frequent absence of assistants, the isolation of the patient, and the difficulty of always having a proper atomizer in working order. It is therefore very fortunate that the spray is not essential in the majority of cases, to the success of the method.

In the larger operations, however, like ovariotomy, its use is always advisable, because if it is not absolutely necessary, it certainly does no harm. And every possible safeguard should be employed in operations of such magnitude.<sup>1</sup>

*To be continued.*

<sup>1</sup>The reader is referred to the works on antiseptic surgery by Cheyne, MacCormac, and Hether, also a volume entitled "The Treatment of Wounds," by F. Huber, for verification of most of the statements made in the foregoing article.

## Original Articles.

### A CONTRIBUTION TO THE MECHANICAL TREATMENT OF DISEASES OF THE KNEE-JOINT.

BY CHARLES F. STILLMAN, M.S., M.D., OF NEW YORK.

*Clinical Professor of Orthopaedic Surgery in the Women's Medical College; Orthopaedic Surgeon to the New York Infant Asylum.*

At the meeting of the American Medical Association, in 1881, the writer exhibited to the Surgical Section a new joint splint and gave a short account of its development, and he also exhibited, before the Section, the Esmarch bracket, which was

Fig. 1.

Esmarch's joint bracket.

in general use by surgeons at the time. This, after being properly fastened to the limb with plaster of Paris, produced fixation of a joint, and yet allowed exposure of the surface, but did not produce traction.

In order to secure the joint firmly, and at the same time exert traction in the axes of the limb, the writer devised a bracket in which the bridge was

Fig. 2.

Stillman's joint bracket.

composed of two slotted flat strips, lying one over the other and connected together by two thumb-clamps, as in Fig. 2.

This bracket, after being fastened to the limb in the same manner as the Esmarch, gave traction and fixation when the limb was in a straight position, and also allowed motion of the joint if one of the clamps was removed; but if it was desired to hold the joint firmly, with the limb at an angle, one clamp did not exert sufficient power to effect this

Fig. 3.

Stillman's joint bracket with one clamp removed.

object, and therefore the sector of a circle slotted in its circumference to correspond to the slots in the flat strips of the bracket was added to the bracket, the centre of the arc being perforated and connected by a third clamp with both slotted strips.

In Fig. 1<sup>1</sup> this sector bracket is shown, and consists of two slotted strips connected to the sector

<sup>1</sup>Fig. 4 represents the brace which was presented to the American Medical Association by the writer.

by three clamps, and when applied to the limb makes a very useful and serviceable joint splint.

Fig. 4.

Stillman's sector joint bracket.

This has proved itself since that time of special service in the treatment of acute inflammatory conditions of the various joints. It has received warm commendation from many distinguished surgeons throughout the country, and as the same bracket or pair of brackets can be used for either of the larger joints, it possesses a wide range of usefulness.

When attached firmly and properly to a limb, extension of a joint can be produced and yet motion may be allowed or altogether prevented without interfering with the extension. Fixation may also be produced at any angle and yet exposure of the surface of the joint for local treatment allowed, and it is therefore a particularly valuable splint in acute conditions of the joints attended by flexion, effusion, and pain, and in general all acute inflammatory conditions requiring perfect rest.

Fig. 5 shows the appearance of this sector splint when applied to the knee with plaster of Paris in a manner similar to that used in securing the Esmarch, but it differs from the latter in usually requiring two brackets, one on each side, instead of one above or below the joint.

In chronic knee-joint disease, however, a plaster-of-Paris dressing is uncomfortable, and cannot be removed without more or less disturbance of the joint. Since the atrophic changes in the muscles render frequent change of dressing an absolute necessity, the writer has been compelled to devise, for cases of chronic joint disease, special forms of apparatus, and this paper will be devoted to a description of the form of brace (see Fig. 6) which he has found most useful in the various chronic inflammatory conditions of the knee.

The treatment of diseases of the knee-joint as a class has, from a mechanical standpoint, been impeded by the difficulty in procuring apparatus which could be used advantageously through all stages of treatment and in every possible condition

Fig. 5.

Showing application of sector bracket to knee.

Fig. 6.

Stillman's knee splint.

which might arise during such treatment, and there has been no one splint which would meet all the different mechanical indications.

One of the most important of these indications is to incorporate in the brace, and to place on either side of the joint (in its transverse pivotal axis), a movement which will allow either fixation or motion.

Fig. 7.

Stillman's joint movement for fixation or motion.

In Fig. 7 such a one is shown,<sup>1</sup> and if the pivotal centre is placed in the transverse pivotal axis of the joint, its arc of motion will correspond closely to the arc of motion in the normal joint, and by means of the clamp in the slotted arc the joint may be fixed in any desired position, or by releasing the clamp slightly motion may be allowed.

Another important indication is the occasional employment of traction, and a new feature in this splint consists in the method of obtaining it by having adhesive plaster grasp the knee just below and above the joint over a *very limited* area, and to effect this the plaster is cut in the fan shape, shown in Fig. 8 (A), and long strips of webbing are attached to each. It requires four of these fan-shaped pieces for each knee, and four long pieces of webbing, and these are to be placed as shown in Fig. 8 (B), interlaced for greater security from displacement, and then covered with roller bandage as in Fig. 9. Upon the superior and inferior extremities of the splint are provided rollers and buckles, to which the webbing is to be attached, and then, by means of an elastic ratchet, force may be applied upon the thigh portion of the instrument to effect the extension (see Fig. 10).

<sup>1</sup>For description of this movement, see the Boston Medical and Surgical Journal, Vol. C. I. 1887, p. 560.

This arrangement differs from any attachment in ordinary use at the present time, in being limited to a small zone just above and below the joint, and consequently does not interfere with the muscular structure of the thigh or leg, as is the case when

(a) Fan-shaped pieces of adhesive plaster, with webbing attached, for traction.  
(b) The same applied to limb, internally.

(c) The same covered with roller bandage, ready for the splint.

the splints are applied by adhesive plaster over the whole extent as in other splints for this purpose, or in the former plaster-of-Paris attachment of the writer.

To exert the traction and produce extension of the joint, the ends of the webbing strips are to be passed over the rollers at each extremity of the splint, and, after being pulled upon as firmly as possible, are secured in the buckles provided for that purpose.

The upper thigh girth is then pushed away from the remainder of the apparatus either by elastic or rigid ratchets, as the surgeon prefers. The ratchet shown in Figs. 6 and 10 consists of two overriding slotted strips, which can be fastened together by a screw-clamp, when sufficient traction has been exerted by the elastic strap provided for that purpose.

This form of ratchet is a modification of the original Davis elastic ratchet, and in the hands of the writer is more effective than any other traction ratchet he has used, because by simply loosening or tightening the clamp (the elastic strap being on the stretch at the same time), the traction may be varied from the elastic to the fixed at the will of the surgeon, and I have found that if the elastic be kept up unvaryingly, as a result the adhesive plasters are apt to cut into the skin in very much the same manner and on somewhat the same principle characterizing the action of an elastic ligature.

This is obviated without impairment of the efficacy of the traction by simply tightening the clamp holding the slotted strips together, when the desired amount of extension of the joint is secured.

Fig. 10.

Stillman's knee splint applied.

Another indication, also, of the utmost importance in the treatment of knee-joint disease is the prevention of posterior luxation.

Most of the diseases of the knee-joint are accompanied by a tendency, even in the milder cases, to luxation of the tibia backward, and this is a feature which the mechanicians of orthopaedic surgery have tried to overcome with more or less success.

To meet this indication the author has devised a new and effective arrangement which brings to bear a spring lever power, which is distinct from anything heretofore used, and operates without interfering with the action of the remainder of the brace. It will be noticed that it is a long, flat steel bar, bent to conform to the back of the leg, and placed posteriorly (see Fig. 6). At its upper end it is attached a semi-girth which presses on the back of the upper part of the leg, and below it is attached to a stirrup, which is itself fastened to the lower girth of the instrument.

This stirrup is provided with a hinge and a socket, so that it may be opened and shut when the rest of the brace is in position, and the forward pressure, which is dependent upon the angle which the posterior lever makes with the rest of the brace, can thus be adjusted by means of a ratchet at the intersection of the lever with the stirrup, without the necessity of removing the brace from the limb. One of the features of this arrangement consists in its availability for all classes of cases in which the least tendency to this subluxation exists, for it can be adjusted to any desired angle, thereby giving any degree of forward power, and this power is brought to bear precisely where it is wanted, and without causing impingement of the brace upon the limb at any point.

There are very few cases of joint disease, even of the simplest form and of the most recent date, in which the comfort of the patient is not increased by having a certain amount of forward pressure just below the popliteal space.

How many of these patients say to the surgeon that they feel they could walk if they "had something that would press the leg forward just below the knee, as it seems weak at that point"; and by the arrangement shown, this power can be supplied without interfering with the main portion of the brace or with the motion of the joint. There is no form of knee-joint disease in which this forward pressure, either in a lesser or greater degree, is not of advantage, and there is an anatomical reason for this, since in these diseases, relaxation of the quadriceps femoris is accompanied by a contraction of the biceps, semi-membranosus, and semi-tendinosus muscles, thus interfering with the possibility, in many cases, of producing linear trac-

tion in the proper axes of the thigh and leg; while if the tibia is held forward in the position it would be if the anterior muscles were exerting their normal power, the extension of the joint is effected without pain to the patient, and the traction is exerted in the proper axes.

By means of a ratchet at the intersection of the inferior extremity of the posterior lever and the stirrup to which it is attached, this power, as has been stated, can be adjusted so that the lever can be varied from a mere upright support to a spring lever of tremendous force, and in every case in which it is applied (provided, of course, that the power exerted is not beyond the proper amount necessary for the particular case) the patient's usual comment is to the effect that the comfort of the apparatus is thereby much increased; and from the surgical standpoint the joint is placed in much better condition for curative treatment, because this tendency to backward luxation is thereby greatly overcome. This is but another application of the V-shaped lever which the writer is using in the treatment of diseases and deformities of the back and other portions of the body.

In conclusion, after the traction has accomplished its purpose and extension of the joint is no longer necessary, the splint is so arranged as to permit the removal of the rollers and buckles at each extremity and of the traction ratchets, thus converting it into an effective simple fixation splint or knee support during the stage of convalescence, and when by the use of restorative measures the anterior muscles of the thigh have been strengthened so as to hold the tibia forward in its proper axis with the femur, the V-shaped lever may also be dispensed with, provision being made for that purpose without impairing the efficacy of the rest of the brace.

A description of the means to be employed for the restoration of these muscles constitutes too important a subject to be discussed in the limits of such a paper as this, and I shall reserve it for some future occasion. Suffice it to say, that the neglect of this precaution is not only a fruitful source of the long-continuance of lameness and feeble circulation in the entire limb, after cessation of all actual disease in the knee, but it is a cause of relapse, and the importance of this factor is too little, if at all, insisted upon by orthopaedic writers in treating of the subject.

#### CASES OF CEREBRAL SYMPTOMS IN EARLY (SECONDARY) SYPHILIS.

BY F. B. GREENOUGH, M.D.,

Physician to the Boston Dispensary, Department of Skin and Venereal Diseases.

THAT syphilis at the present time, on the whole, is a milder and less virulent disease than it was formerly is a fact which, I think, cannot be questioned. Whether this is due to a change in the type of the disease itself, or to an improved and more rational method of treatment, is perhaps an open question, but probably both of these factors have a share in the change that has taken place. That there has been a change is shown by the fact

that while without doubt the number of cases of syphilitic disease has been increasing, the number of cases where we find serious and destructive lesions of the skin and mucous membranes have diminished. This is, of course, simply a statement of opinion, not corroborated by statistics, but I think the opinion I express will be endorsed by colleagues who have seen much of venereal practice. Of one thing there can be no doubt, and that is that at present many, that is to say, a large percentage, of the cases of syphilis do very well, and after the comparatively light symptoms of the secondary period have passed off do not hear from the disease again. I am aware that it is claimed that the disease is not eradicated, but simply latent; but if it continues latent during the rest of the patient's life, and has no influence either on him or his offspring, what a boon it would be to humanity (as Helbra used to say) if phthisis, cancer, and other diseases could be made latent to the same extent. That the less frequent occurrence of severe sequelæ from syphilis is not entirely due to improved methods of treatment is shown by those cases in which, either from recklessness or indifference, or any other cause, the patient has stopped treatment long before he would have been advised so to do, and yet has for years been free from all symptoms. Although I have not attempted to get the exact figures, I can say that during my fifteen years' experience in charge of the special department at the Boston Dispensary the number of cases that showed late and grave lesions of syphilitic disease compared to those that came for treatment for the early symptoms has been very small. And yet these patients are exactly of the class in which one would expect bad results. That is to say, they are poor, unable to get proper food and care, often of bad habits, and rarely follow out the instructions and treatment given them for the length of time that in private practice would be insisted upon. While, however, the number of cases of syphilis that are followed by serious later symptoms seems to have diminished, or at least to be comparatively small in number, those in which we find evidence of cerebral trouble have decidedly increased. To convince one's self that this is the case one has only to look at the medical literature of the last decade and compare it with that previous to the last—twenty, or even fifteen, years. With regard to the recognition of cerebral syphilis by the older authors there seems to be some difference of opinion. Legrand du Saulle, in the *Gazette des Hôpitaux*, in an article on "Cerebral Syphilis," says: "The first notions with regard to the cerebral symptoms in cases of syphilis date back very far. Fraenstor and Nicolas Massa even say decidedly that the French disease may be accompanied by insanity and epilepsy." On the other hand, Heubner, in his very complete article in Ziemssen's *Cyclopædia* on "Syphilis of the Brain and Nervous System," says: "Although Fraenstor described so graphically the ravages of syphilis on the face, etc., he knew nothing of the internal diseases of the same patients." He also states that this lack of knowledge with regard to syphilis of the nervous system was due, in part, to the fact that the old practitioners occupied themselves chiefly with symptomatology and therapeutics. This may be very well

as far as the Middle Ages go, but when we see that John Hunter classed the nervous system as one of the vital parts which are not at all susceptible to the action of syphilis, and that Ricord, in his classical "Letters on Syphilis," does not refer to this subject, it certainly looks as though not many cases of the kind I am about to report could have come under their observation. As late as 1861 Professor Lasèque, as the result of his investigations, reported to the Faculty of Medicine in Paris that "the nervous manifestations of syphilis are rare, indistinct, and destined, at least until further investigation, to figure in an account of syphilis as an appendix." It was just about this time, that is, 1861-62, according to Heubner, that scientific investigations with regard to cerebral syphilis began to be made. The monographs of Léon Gros, Lancereaux, and Lambuco marked out the path for study, and they were followed in Germany by Jaksh and many others. Fournier in 1879 published his "Syphilis du Cerveau," which, while it may not be up to the later German authors as far as pathological anatomy goes, is certainly a most wonderful collection of clinical observation. I will merely make three quotations from his preliminary chapter to show his deductions from his vast amount of material as to the frequency of cerebral syphilis at the present time, and ask you to remember that John Hunter considered the brain as non-susceptible to syphilitic disease, and that Ricord does not mention the possibility of cerebral syphilis. Fournier says: "A case of hemiplegia occurring in a subject less than forty years old, not affected by alcoholism, nor suffering from a lesion of the circulatory system, is, in eight cases, or perhaps even nine cases, out of ten, of syphilitic origin." Again: "When epilepsy manifests itself in a subject over twenty-five or thirty years old, for the first time, in nine cases out of ten it is of syphilitic origin." Finally, according to him, at least seventy-five per cent. of cases of ocular paralysis are due to syphilis. To even give a list of the literature on this subject during the past five years would exhaust your patience, so I will simply state that it is a very rich one, and that whatever minor differences there may be between the different authors, they all agree on one point, and that is that cerebral syphilis, as a rule, is one of the later manifestations, that is, that it is a symptom occurring in the so-called tertiary stage of the disease. Whoever was responsible for the terms primary, secondary, and tertiary did a very poor service to syphilography. From the meaning of the words one would naturally suppose that they were three distinct stages of the disease, one following the other. As a matter of fact, in many cases the primary lesion still exists when the secondary symptoms appear, and secondary and tertiary symptoms are more frequently than not seen coexisting. I happen to think of a dispensary patient who has now mucous patches of the tongue, such as are frequently seen during the early outbreak of constitutional symptoms, who two years ago had typical muscular gummata. Neither can a distinction be made according to the tissues affected, as yet infrequently the periosteum is the seat of the very earliest secondary manifestations. There are, however, two distinct sets of symptoms in syphilis,

one of which, as a rule, is decidedly later in its appearance, and these are the symptoms of the different tissues that are due to an inflammatory process, which may range from simple congestion, as in the case of a macular syphilitic, or in congestion of the fauces, through infiltration (papular eruptions), desquamation, and ulceration; and, on the other hand, those that result from the development of a neoplasm, or gummy tumor. It seems to me that if we are to use the term tertiary at all it should be confined to these latter manifestations.

To return, however, to cerebral syphilis. As I have stated, the evidence of the authorities is that it occurs, as a rule, as a late symptom, but in the more recent literature we find that exceptions to this rule are recorded. Fournier gives from the third to the eighteenth year (after infection) as the most common period for cerebral manifestations, and puts two thirds of the cases between the third and tenth year, and one third between the tenth and eighteenth. He says, however, that "cases have been seen during the second or first year of the disease, even as early as the seventh, sixth, or fifth month." "These are, however," he goes on, "I hasten to say, rare facts, and naturally all the more rare as the date of the manifestation is more precocious." Heubner states that from his figures, that is, from the statistics derived from the cases observed and collated by him, it appears that when a syphilitic growth is developed in the nervous system such a growth almost invariably appears at a late period; in fact, when the syphilis has lasted for several, or often many, years. This rule, of course, he says, is not without exceptions. Prof. H. C. Wood, in an article on the "Clinical Aspects of Cerebral Syphilis,"<sup>1</sup> gives a very full account of the subject, more especially with reference to the later manifestations, epilepsy and general paralysis. He says, however: "Although syphilis is most prone to attack the nervous system many years after infection, it would be a fatal mistake to suppose that brain disease may not rapidly follow a chancre."

Legrand du Saulle, in a series of articles published in the *Gazettes des Hôpitaux* in 1884 (vol. lvii.) on "Cerebral Syphilis," says: "At what period of the disease do the cerebral symptoms show themselves? In a general way, it can be said, in the tertiary. Ordinarily they show themselves from three to ten years after the primary lesion. But they may be delayed and not appear until after an interval of twenty to thirty years. Sometimes, however, in cases of precocious, malignant syphilis, they form part of the secondary symptoms."

Not to take up time by more quotations, I will state that the mass of authors on the subject agree with great unanimity on the fact that cerebral syphilis is of late development, and that, although there are exceptions, cases which show affection of the nervous centres within the first year are decidedly exceptional. It is this unanimity of opinion that has made me think that the five cases that have come under my observation during the last few years, in which symptoms of syphilitic cerebral trouble appeared quite early (the average of the five cases being a little more than five months),

<sup>1</sup> Boston Medical and Surgical Journal, 1884, vol. cx., Nos. 9 and 10.

were worth reporting. While our standard textbooks give very good descriptions of cerebral syphilis, and speak of the possibility of its occurrence, exceptionally, quite early, they do not sufficiently, if at all, call attention to the indication for the modified course of treatment which such cases, I think, imperatively show. The number of cases reported of precocious cerebral symptoms, while small compared with those in which the cerebral lesions came on late in the disease, are, in recent literature, fairly numerous. Fournier reports a dozen or more. Dr. Webber, in his paper presented to this Society, reported some precocious cases, that is, one of ten months, one eight to nine months, and one a little over three months. I find a case reported in the *New York Medical Journal* (1884, xv. p. 430) as a "Case of brain disease" (probably syphilitic), by Lucy M. Hall, M.D., and it is one of the very few in which a careful autopsy was made and recorded. Unfortunately, it may be objected to the case that it is not absolutely proved that it was a syphilitic one. I will give an abstract of it: The patient was a girl of sixteen, an inmate, I infer, of the Reformatory Prison for Women at South Framingham. The first record is December 1, 1883. No special symptoms, but poor appetite, pale, and nervous. January 24, 1884, some general febrile disturbance, high pulse and temperature, with pain in left temporal region, and vomiting. The pain in left side of forehead was constant, and unyielding to treatment. February 4th small excavated ulcers were noticed on side of tongue, and she was dull, stupid, and somewhat comatose. February 17th, tongue was swollen, left half being half (*sic*) dry, right half moist; the mouth was drawn to right side slightly, and partial paralysis of the facial muscles of the left side was noticed. She died at midnight. The autopsy showed the organs in the pelvic and abdominal cavities to be normal. There was thickening both of the dura and pia, and the cerebral vessels were distended, especially on the left side. "Fallow-like bodies, from the size of a millet-seed to a grain of wheat, were found along the surface of the dura in the line of the longitudinal sinus; also in the region of the third frontal convolution on the left side. The bases of the second and third convolutions on the left side were so soft that the handle of the scalpel laid lightly upon them penetrated the brain-substance. Section of the left anterior cerebral lobe showed a partially absorbed hemorrhagic infarction of the third, or Broca's, convolution, occupying about half its extent. If this was a case of syphilis, the age of the subject, sixteen, shows that it must have been of not long standing.

From Professor Wood I will quote the following cases of precocious cerebral symptoms: Dr. Alfrik Ljunggren, of Stockholm, reports a case where a rapidly healed chancre in March was followed in May by severe headache, mental confusion, and giddiness. Early in July (four months) he had an epileptic attack. This case was cured. Davaine reports paralysis of the portio dura a month after the first symptoms of constitutional syphilis. Dr. E. Leyden found advanced specific degeneration of the cerebral arteries in a man who had contracted syphilis one year previously. Dr. R. W. Taylor

reports a case where epilepsy occurred five months after infection. Dr. Schwarz's case had severe headache forty days after the development of the primary lesion, and on the forty-sixth day hemiplegia. Another case had an apoplectic attack seven months after the chancre, a female patient one five months after the appearance of her primary lesion. Dr. A. Sydney Roberts's (Philadelphia) case had a fit two months and eight days after the appearance of a chancre, which developed after a period of incubation of twenty-six days. Unmistakable cerebral syphilis followed, but convalescence under active antisymphilitic treatment.

These are some of the cases of early cerebral syphilis that I find record of, and are enough to show that, although rare, precocious cerebral syphilis is recognized. The following cases that have come under my own observation I will report in as condensed a manner as is consistent with calling attention to their important points.

CASE 1. On July 5, 1878, I was visited by a gentleman for advice. He was a lawyer, aged thirty-eight, reported his health as good, and appeared to be a strong, healthy young man. About two weeks after connection he had noticed a sore on the prepuce, which at the time of visit was a typical primary syphilitic lesion. The induration was well marked and quite large, and the inguinal glands in both groins were enlarged. In the latter part of August he had some soreness and congestion of the fauces, and on September 7th a macular syphilide appeared on his trunk and thighs. The eruption was not a very full one, and was entirely macular. In October he had some manifestations of secondary symptoms on the mucous membranes, that is, sore throat, with some congestion of the fauces, superficial plaques on the tonsils, and slight lesions on the sides of the tongue. He was put on a mercurial course of treatment from the first appearance of the constitutional symptoms, and seemed to be having a very mild case, until (some time in September) he began to be troubled with headaches, which came on in the afternoon, were aggravated toward night, and became very severe. These were relieved for a time by the iodide of potash, and it did not require very large doses (ten to fifteen grains three times a day) to control them. During October, November, and December I saw him about once in two weeks, and with the exception of an occasional attack of cephalalgia, lasting for two or three days, and yielding to increased doses of the iodide, which, however, never exceeded twenty grains three times a day, he seemed to be doing very well. The eruption had faded out, and the mucous membrane of the throat and mouth was healthy. I have heard since, however, that his friends noticed that he was heavy and sluggish mentally at this time. On December 27th he called, his previous visit having been on the 9th, and while there were no definite symptoms, except a more persistent headache, it was evident that he was not doing well. Besides increasing his dose of iodide, I thought it best to increase the action of his mercurial treatment, and as he objected to the use of inunctions I put him on small and frequent doses of calomel, and he was asked to report in a few days.

I did not see him again, as he came under the care of the family physician after that time, by the kindness of whom I am enabled to condense the following record from his very full notes on the case:—

On January 6, 1879, that is, ten days after I had seen him, while at dinner, he felt that he had lost power over his left leg. It was not completely paralyzed, but he could barely move it, and he was taken up to his room. On being questioned, he said that on the 14th, two days previous, he had noticed a prickly feeling in his right hand, and some loss of power in the fingers, shown by difficulty in using his pen. Also some dull headache. This loss of power in the right hand was more noticeable on the next day, and on the next one, that is, January 6th, the decided, but partial, paralysis of the left leg came on while he was dining with his family. On the 7th, that is, the day after his attack, in trying to get about his chamber he fell, and is reported to have been quite shaken up by his fall. The cause of his trouble being suspected by his physician, he was asked with regard to his previous syphilis, and gave a very good account of his disease, both as to symptoms and treatment. The paralysis of the left leg increased, and his mind became sluggish, although he would answer questions when aroused. The sphincters of the bladder and anus became paralyzed, as was shown by involuntary passage of urine and feces, and on the 12th it was noticed that there was paralysis of the left facial muscles, the mouth being drawn to the right side. On the 13th complete paralysis of the left upper extremity was evident. His mind was wandering, but he would answer when roused. On the 18th he was delirious, and muttering about matters that he was interested in, and died quietly at 5.30 p.m., twelve days after his attack of paralysis of the left leg. The specific origin of his attack was recognized from the first, and he was given a most thorough antisyphilitic treatment. Iodide of potassium was given in increased doses, as well as mercurial inunctions.

A careful examination of the brain was made, but the full record of it cannot be found. In the case-book of the attending physician the fact that there was thickening of the pia at both vertices was noted, as well as a partial plugging up of some of the cerebral arteries by means of an apparently new formation. He, however, simply noted these main points, referring to the source where he supposed the full record could be found.

CASE II. I saw this patient, a civil engineer, aged twenty-one, first on January 13, 1883. He was tall, thin, not well developed as far as muscular development goes, but reported his general health as good. He consulted me on account of a lesion which had appeared on his penis after intercourse, which proved on examination to be a primary syphilitic chancre. The induration was well marked, as was the enlargement of the lymphatic glands in both groins. Under the topical use of iodoform the chancre healed, and on April 1st a pretty generally distributed macular secondary eruption broke out. There was also at that time some congestion of the fauces. He was put on a mercurial course of treatment, and when seen on April 19th the eruption

simply showed some spots of pigment; the mucous membranes were healthy, but there were some small crusts scattered over the scalp.

On the 21st of May I received a letter from him from an inland town, where he was engaged in professional work, stating that he had been for some days troubled with a very severe headache, which was much aggravated at night; that he was very feverish, and felt generally very unwell. I wrote to him to take ten grains of iodide of potassium three times a day, and to report as soon as possible. On the 24th, that is, three days afterward, he came to my office in what certainly seemed a very critical condition. It was with difficulty that he spoke, his mouth being drawn to the left side during articulation, and his gait was very unsteady. He reported that after writing to me his headache was so excruciating, and feeling a decided numbness of his right side he had consulted a local practitioner, and by his advice had taken a cathartic and Dover's powder. On receipt of my letter he had begun on the iodide, and although his severe headache had ceased, as he had great difficulty in enunciation and noticed a decided loss of power in, and control of, his right arm and leg, he had come to see me. In addition to the partial right-sided muscular paralysis he had double vision. His symptoms improved gradually, and by June 15th, three weeks after, he was apparently all right, and has had no relapse since, having been under treatment and observation up to date. He is now doing his work as a civil engineer, is able to do it, and weighs more than he ever did.

CASE III. This patient, a student, aged twenty, consulted me July 12, 1883, for a urethral trouble, complicated with an acute epididymitis. He was small in size, pale, and, as far as muscular development goes, decidedly below par. He dated his gonorrhoea back to the middle of the previous December, and stated that shortly after his gonorrhoea had appeared he noticed a sore on the penis, which proved to be a primary syphilitic lesion, and which was followed by secondary constitutional symptoms. These had entirely disappeared by the time of his first visit to me; but from his report, which, by the by, was a very clear one, they must have been quite mild, and have yielded readily to treatment. His urethral trouble did well, and is of no interest in this connection, but his account of his syphilitic infection was so clear and consistent that I felt it my duty to put him on specific treatment, in the propriety of which I was confirmed by the appearance, later, of slight mucous patches on his tongue. He was doing very well when I saw him on July 28th, and on October 8th, when I saw him after his return from his vacation, he made the following report: On August 26th he had what was considered a sunstroke, as a result of which he was laid up in bed for a week, and was "under the weather" for some time more. On investigation, the "sunstroke" was reported to have come on two days after the supposed cause, that is, playing tennis in the sun, and getting much fatigued. He had had severe headache for some days previously, which was worse toward evening. His first symptom was a feeling of giddiness, in which he stumbled, and felt that he had lost control of his muscles. He had difficulty

in articulation, and even when seen October 8th I noticed a decided difficulty or hesitancy in his speech. For some time after he got about he reported a tendency to stumble, and at times a feeling of numbness in his left arm. Under a mixed treatment of a mercurial and iodide he improved in general condition and gained in weight. On November 28th he reported having had for a few days a very severe headache, which ceased at once on increasing his dose of iodide. In February, 1884, he went to the Hot Springs, Arkansas, where he went through a thorough course of inunction, and returned about the middle of April, having gained flesh and strength, and showing no specific symptoms. He is still under observation and treatment.

Although this case was not seen by me, either during the first outbreak of syphilis or at the time of his partial paralysis, I do not see how there can be a question as to the connection of the two. He did show decided and unmistakable symptoms of constitutional syphilis, that is, mucous patches on the tongue, and his account of the appearance of the sore on his penis, in December, followed by constitutional symptoms, which under treatment disappeared, was so precise as to leave no doubt in my mind as to the date of contagion. His account of his supposed sunstroke, eight months afterward, was also very clear, showing that he had had an attack of vertigo and loss of power over his limbs and speech, the latter symptom not having entirely passed off when I saw him about six weeks later, which attack was referred to an exposure to the sun and fatigue, two days previously. As additional evidence, there is the fact of these attacks having been preceded by headaches, with nocturnal exacerbations, and that since then he has had headache of the same nature, which has yielded at once to a course of iodide of potassium.

CASE IV. A mechanic, aged thirty-eight, consulted me on January 2, 1884. The patient was a tall, heavily framed man, but very much reduced in flesh and anemic. About the middle of the previous August he had a sore appear on his penis, which was at first supposed to be a chancre, but it was followed by symptoms of constitutional syphilis, and as he did not agree with his physician's diagnosis he put himself under the care of one of our quack institutes. When seen he showed marked symptoms of quite severe secondary syphilis. He had a very generally distributed papular, crustaceous eruption on his trunk, limbs, and scalp, as well as decided mucous patches on his tongue and tonsils. What he complained of most was an excruciating headache, worse at night, which had continued for some days. He reported that on several occasions, while at work, he had had "giddy spells," in which he had stumbled about, and two or three times had actually fallen down. At these times he had lost the power of speech, by his report, and in this respect he was confirmed by the gentleman, one of his employers, who brought him to see me. He was heavy and dull, and was evidently suffering from severe pain in his head at the time of his visit. He was put on a course of mixed treatment, that is, the bichloride of mercury and the iodide of potassium, and the lesions of the cutis and mucous membranes improved at once, but his cephalalgia was

more obstinate. It did yield, however, to inunctions, combined with the iodide, but as his gums showed decidedly the action of the mercury these had to be suspended. He also showed a sensitiveness to the iodide, having a very copious eruption of acne on his back and chest, as well as on his face, and a decided coryza. By carefully regulating the dose, however, he was kept on a mixed treatment, and by March 12th, about two months after he was first seen, he had gained twelve pounds, and his headache was reported to be a thing of the past. He is still under treatment, apparently well, and able to do his work.

CASE V. I first saw on May 23, 1884. The patient was a thin, nervous man, aged forty-three, interested in manufacturing, and evidently much upset by the trouble for which he sought advice. A few days after exposure he had noticed a lesion on the glans penis, which he had treated by an application of strong carbolic acid. The result was an inflamed, indurated sore, covered by a sloughy, whitish eschar, with some glandular reaction in both groins. As, owing to the artificial irritation from the application he had made, the diagnosis was rendered doubtful, no decided diagnosis was given. Under soothing local treatment the acute inflammatory condition passed off, but even after the sore had healed some induration remained, and the inguinal glands, instead of diminishing in size with the subsidence of the inflammation, became larger. On July 5th (six weeks after he was first seen) he had a quite fully developed macular syphilide, and was put on a mercurial course. The eruption was simply macular, and disappeared rapidly, as on the 19th, that is, in two weeks, no traces of it were to be seen. As his symptoms disappeared his fussiness about himself seemed to increase, and it was with the greatest difficulty that he was made to continue his treatment. On October 2d, while showing no symptoms, he complained of having had, on two occasions, very severe headaches, and was ordered the iodide of potassium in addition to his mercurial. He was seen three times between then and the 28th, when he protested so strongly against the iodide, which, he said, he was sure did not "agree with him," as he had omitted it for a day or two at intervals, always with good results, that I stopped it, and substituted a simple tonic. I was induced to do this as, although he had more or less cephalalgia, he insisted that it was not constant, or aggravated at night, and felt sure that it was connected with indigestion, which he laid to the iodide. On the 30th, two days afterward, he entered my office, and I thought he would tumble on the threshold. He stumbled into a chair, and, after a good deal of twitching of his mouth, managed to articulate, "I am paralyzed!" After a few moments' rest his articulation improved, and he was able to give an account of himself, but there was undoubted partial paralysis of the muscles of speech, and his mouth was drawn, in speaking, to the left side. He said that he woke up that morning with a feeling of numbness in his right arm and leg, and difficulty of speaking. There seemed to be a loss of power in the right arm, as tested by the grasping-force of the hand, and the right leg seemed to drag in walking. His difficulty in speaking was, however, the

most marked symptom, and although that improved after he had been sitting quietly in my office, it was very decided. His condition was almost an exact counterpart of Case No. 11. As he was a stranger, at a hotel, I advised him to take a room at a hospital, and he was admitted to the City Hospital, and came under Dr. Webber's care. Dr. Webber has reported his case before this Society in full, and as it will be published in the coming report of the City Hospital, I will merely say that under mixed treatment the patient recovered, and that I have seen him since, free from specific symptoms and apparently well.

(To be continued.)

## Reports of Societies.

### AMERICAN CLIMATOLOGICAL ASSOCIATION.

THE PRESIDENT appointed as Nominating Committee Drs. Shattuck, Reed, Westbrook, Hudson, and Wilson.

#### EVENING SESSION (MAY 27TH).

THE PRESIDENT, DR. A. L. LOOMIS, in the chair.

A new instrument for the removal of adenoid growths in the pharynx was presented by Dr. W. C. JARVIS, consisting of a form of steel cup with a shank. By pressing the mouth of the cup over the tissue surrounding the growth, the snare could better grasp the base.

Dr. Bosworth had had no practical experience with the instrument, but if it accomplished what was claimed for it, it would be of great advantage. He added that the more he saw of catarrh in children the more firmly did he become convinced that its cause was usually due to adenoid growths in the pharynx, and not to inflammation of the mucous membrane of the nasal cavity proper.

#### FURTHER CONSIDERATION OF PNEUMATIC DIFFERENTIATION, WITH DEMONSTRATION OF THE PNEUMATIC CABINET.

Dr. H. F. WILLIAMS, of Brooklyn, read the paper. The original article on the subject was published in the *Medical Record*, January 17, 1885, to which he referred the reader for a more complete exposition of his subject. His method consisted essentially in making the patient breathe the normal atmosphere through a tube, while the air within the chamber where he sat was more or less completely removed, producing a partial vacuum. This method induced deep respiration, or, by relieving pressure from without, caused the air to thoroughly permeate the lungs. Medical vapors could be mingled with the inspired air, and would thus be more likely to reach the seat of the disease.

The five cases of phthisis reported in the former article as cured remained apparently well to-day. Six cases of primary infiltration remained in perfect health, with one exception. This patient took a cold, but was again improving under treatment. Paradoxical as it might appear, great benefit was produced in three cases of emphysema. Altogether, seventy-five cases had been treated by this method in New York and Brooklyn by different physicians, and it promised to be of great usefulness.

(Continued from p. 551.)

THE PRESIDENT said, one patient whom he had treated, and who had always been compelled to leave the city during the winter, had fallen into Dr. Williams's hands, and had been enabled to remain at home this season. He knew of no case in which hemorrhage occurred after the treatment excepting the one referred to by the author of the paper, and in that instance it occurred twenty-four hours after the last treatment, there having been thirty altogether. The patient thought that the gentleman who had charge of the apparatus at the time allowed too much pressure; otherwise he thought it could have had no deleterious influence.

Dr. ARMOUR, of Brooklyn, spoke of a case of unresolved pneumonia in which the treatment had brought about marked results.

#### THE HOME TREATMENT OF CONSUMPTION

was the title of a paper by Dr. F. C. SHATTUCK, of Boston. The subject was introduced by a quotation from a French professor who ten years ago remarked, while making his hospital visit, that the only remedies for consumption are opium and lies. With this remark was contrasted the opinion of Jaccoud that phthisis is curable in all its stages, the experience of Dr. Flint which has led him to the view that some cases of phthisis are self-limited, and also that of most physicians in active practice. A more hopeful view is certainly current among the profession now than was formerly the case. The lessons to be derived from a study of the Massachusetts Registration Reports from 1857 to 1883 were then briefly alluded to. In the former year 39,500 deaths from consumption occurred for each 10,000 of the population, in the latter 29,90; and this in spite of the influx of foreigners, among whom the Irish are specially prone to consumption. The reader thought that this marked decrease was chiefly attributable to prophylaxis through improved hygiene among the native-born; but that a portion should be credited to earlier diagnosis and more rational treatment.

Treatment proper was considered under the main heads, the hygienic and the medicinal; the former including food, dress, moral management, fresh air, rest and exercise, and bathing. Each of these was briefly dwelt upon, and the medicinal treatment was then taken up, a distinction being drawn between the general medicinal, tonic, or curative remedies, and those which are given simply to combat symptoms, such as cough, night-sweats, pyrexia, and the like. The importance of refraining from prescribing cod-liver oil if there is fever, or the patient cannot digest it, was insisted on; in disturbed states of the stomach it being often desirable to prepare the way by a vegetable bitter and sometimes laxatives. A protest was entered against the use of cough-medicines, so called, most of which tend to impair the digestion, unless the cough provokes vomiting or breaks the night's rest. The peculiarities of the cough are to be studied in each case, and routine treatment here as elsewhere to be avoided as far as is possible. The reader stated that he purposely omitted any special reference to the inhalation and pneumatic treatments, and had not been sufficiently favorably impressed by the results of Pepper, Robinson, and others to lead him

to try the injection of the lung by antiseptics. The subject of the home treatment of consumption is so large that it was possible to give only an outline sketch within the limits of a single paper.

DR. KRETZSCHMAR coincided in the line of treatment recommended by the author of the paper, but said he thought particular attention ought to be given to the ventilation of the bedroom of the consumptive at night, and the habit which usually existed among the poor of a number sleeping in the same room ought, if possible, to be obviated. Again, the sputa of the phthisical patient were often allowed to remain too long in the room, or to fall upon the floor.

DR. ROBINSON thought the paper was an admirable presentation of the subject of the home treatment of consumption. He would add to what had been said that forced feeding might prove of benefit in some cases. He also referred to antiseptic inhalations, which he had treated of in his paper.

DR. SHATTUCK, in closing the discussion, said he agreed with what had been said by Dr. Kretzschmar, and the points made by him and by Dr. Robinson were not more fully treated for want of space.

#### SECOND DAY. — MORNING SESSION.

The President in the chair.

#### A RULE FOR THE EVEN DIVISION OF CLIMATE, BASED UPON THE AVERAGE OF THE COMBINED ATMOSPHERIC HUMIDITIES IN THE UNITED STATES.

By CHARLES DENISON, M.D., of Denver, Colorado. In the absence of the author, the paper was read by Dr. J. H. TYNDALE, of New York. Maps were exhibited, illustrating the range of temperature and the mean of temperature, the amount of humidity, the force of the wind, etc., in the different parts of the United States, as based upon the reports of the signal service bureau. These qualities of the climate were indicated on the map by different shadings, lines, etc. Dr. Denison's view was that the principal elements of a desirable climate were dryness, elevation, and equability of temperature. Of these three, dryness was considered the most important, equability next, and elevation third, which was not to be separated from dryness.

The President said he had received a set of the maps, and it appeared to him that Dr. Denison had endeavored to put too much upon them, which was confusing. As stated in his address, he thought humidity depended more upon the soil than upon the general condition of the atmosphere as defined by Dr. Denison. The importance of the formation of the soil as influencing humidity has also been considered by Dr. Bowditch and others. One might suppose from the general appearances of the Adirondack region that it would be very unwholesome for those suffering from phthisis, yet the contrary had been shown to be the case, and this depended upon the sandy soil and free drainage which rendered the atmosphere pure.

DR. A. N. BELL thought that dryness of the atmosphere at certain places as indicated on the maps went little toward insuring the inhabitants immunity from phthisis. In Colorado, for instance, the mortality from phthisis was about the same as

in Florida and certain other portions of the South, the humidity of the atmosphere being represented on the charts as much less in Colorado. That something else than moisture had an influence upon the consumptive was made plain by the fact that at many places on the seacoasts there was less phthisis than inland, where the humidity was slight. The great freedom of seamen from phthisis was, making due allowance for their better physical development and other conditions, to be accounted for only by the fact that moisture alone should not be regarded as the all-important element in the causation of that disease. While he admired the industry shown by Dr. Denison, he was far from willing to accept his suggestion to make excessive dryness, to say nothing about altitude, the test of climate for the consumptive.

DR. REED agreed with what Dr. Bell had said, and called attention to the fact that in the English army, composed of picked men, the death-rate from consumption was much greater than in the navy, also composed of picked men.

The President said it was evident from the tone of the discussion that the Association was not willing to endorse Dr. Denison's position, and it was hardly necessary to take a vote upon the subject.

#### GEOGRAPHICAL DISTRIBUTION OF PHTHISIS IN MICHIGAN, WITH SKETCH OF TOPOGRAPHY.

By E. L. SHURLEY, M.D., of Detroit.

In the absence of DR. SHURLEY, DR. J. B. WALKER read the paper. Michigan could be divided into two regions, in which the climate differed: first, the northern, or mineral, region; and second, the southern, or agricultural, region. In the northern section the altitude was higher, the soil was sandy; there were pine forests. The climate of the whole State was temperate, rendered so by the surrounding lakes. The mortality from consumption in the different parts of the State for a number of years was then given. In parts of the north there were scarcely any deaths from this disease.

#### THE TREATMENT OF LARYNGEAL TUBERCULOSIS.

by E. F. INGALLS, of Chicago, was read by title.

#### THE PROBLEM OF ACCLIMATIZATION.

DR. J. H. PLATT, of Brooklyn, read the paper, in which he gave definitions which had been proposed for this term, and spoke of the difficulties which surrounded the study of the subject. Illustrations of the influence of a change of climate upon people were quoted. It was but natural that changes in the animal economy should take place on removing from, for instance, a temperate to a tropical region. The lungs being less called upon to do work under the new conditions would be less developed, the skin, which was more active, would manifest changes, and so with other organs. It was probable that the nervous system played an important rôle in the process of acclimatization. In general, a removal to a tropical climate would imply a change in the animal economy approximating more closely that of the herbivora. A perfect knowledge of acclimatization would not be had before physiolo-

gists had demonstrated the exact function of the different organs of the body and of their reciprocal influence. Natural selection was an important factor, for those persons who became acclimatized were most likely to prove reproductive, while those who were unable to adapt themselves to their new surroundings necessarily ceased to propagate.

DR. SHATTUCK wondered that any author had ever doubted the fact of acclimatization. It would be perfectly evident to one who would take a walk in England and then in New England, where both people had common ancestors. He also spoke of the difference of opinion which existed regarding the negro population of the Southern States.

#### SECOND DAY.—AFTERNOON SESSION.

The PRESIDENT, DR. A. L. LOOMIS, in the chair.

#### REMARKS ON THE CLIMATE OF FLORIDA.

DR. J. C. WILSON, of Philadelphia, read a paper with this title. He spoke only of the peninsula of Florida, which he divided into four parts, running in the direction of its long axis. The Atlantic seaboard, the St. John's River, the elevated pine lands constituting the watershed, and, lastly, the Gulf coasts. The two principal characteristics of all these regions were mildness and equability, due to the fact of their lying in a subtropical zone, and between the Gulf Stream on the one side and the Gulf of Mexico on the other. The advantages and the disadvantages of the health resorts on the Atlantic seaboard and on the St. John's River were then pointed out. The elevated region covered by pine forests and well drained would probably become an important health resort for consumptives in the future. The Gulf region possessed special advantages, particularly those of equability and comparative dryness. Ments exposed to the air here were said not to decompose, but to undergo desiccation. An excellent place for a health station was at Port Brook.

DR. TYNDALE thought the facts incorporated in the paper just read went to prove the inferences of Dr. Denison: that equability of temperature, dryness, and elevation covered the other constituents of climate, such as sunshine, wind, and electricity.

#### THE CLIMATE OF CENTRAL FLORIDA.

DR. KEATING, of Philadelphia, read a paper on this subject, in which he described the elements of climate of the elevated regions in the central and peninsular portion of Florida. The ground was elevated, the soil sandy, favoring free drainage, the climate mild and equable, there were pine forests, there was good drinking-water, and while but few hotels as yet had been built, there were towns which afforded good accommodation for the consumptive traveling in search of health. Orlando, a railroad terminus, was a desirable health station. Certain disadvantages of St. Augustine and Jacksonville were pointed out, the latter place being, as he thought, damp and malarial. The author particularly deprecated sending patients advanced in phthisis on long voyages or to distant countries where little or nothing was known of the climate as it affected the consumptive.

#### THE RESULTS OF THE HOME TREATMENT OF CONSUMPTION CONTRASTED WITH THOSE OF CHANGED RESIDENCE AND CLIMATE.

DR. E. D. HUDSON, JR., the author of the paper, said with regard to climate that each individual must ascertain by experience what climate was best suited to him while suffering from consumption, and there reside for three or four consecutive years. The climate which was beneficial to one consumptive might not be the best for another. A change of climate was only a relative term; it did not necessarily involve removal to a great distance from one's home. The wealthy had the advantage in travel, of out-of-door life, of relief from nerve tension, of temporary changes of climate tiding over certain critical periods, etc., and of checking the progress of phthisis until an age when persons were less liable to fall victims to its influence.

The importance of a correct diagnosis of the disease before selecting a climate most suitable for the patient was pointed out. The climate best suited to the several forms of phthisis was mentioned. The greatest benefit to be derived from a change of climate was to be expected in catarrhal phthisis. It was possible for a cure to take place in a case of phthisis with large cavities.

The home treatment of phthisis would consist in a change of environment, from school life to out-of-door life, removal from an old house in which the air was rendered impure by the surroundings, disinfection, free ventilation, stoppage of gas leakage, or bad sewage, proper physical exercise, diet, etc., etc. A large number of cases illustrative of the effect of these different modes of life were given.

#### HAY FEVER AND ALLIED AFFECTIONS.

DR. F. H. BOSWORTH, of New York, read this paper. The chief points made were that hay fever was due to the presence of three conditions: first, a peculiar nervous susceptibility; second, an abnormal condition of the nasal passages, and third, the presence of pollen or other exciting agent in the atmosphere. Any one of these three conditions being absent, a paroxysm could not occur. Dr. Bosworth called particular attention to the anatomy and function of the turbinated bodies, and stated that the very free vascular supply was intended to afford moisture for the atmosphere which passed through the nostrils during inhalation. It had been estimated that the respired air gained five thousand grains of water during its passage over the mucous membrane of the nose. No other mucous membrane of the human body was capable of giving off so great a supply of liquid. The bloodvessels going to the turbinated bones and furnishing this large amount of fluid for admixture with the air were so perfectly controlled by the nervous supply as to regulate the liquid exudation during the sudden changes from a very dry to a very moist atmosphere with great nicety. Any obstruction to the free entrance of the air through the nostrils would tend to rarefy the air behind the point of obstruction, and thus after a time what had been but a trivial condition at first would lead to changes of the greatest importance. Relieve the patient of his nervous susceptibility by building up his general health, and he

might lose his susceptibility to the ragweed or other pollen. Let him go to a climate where such pollen was not present, and he would not suffer from paroxysms of hay fever. Or, cure the morbid state of the nostrils, and thus the paroxysms would be forestalled. It was needless to say that the latter method offered the best prospects of a cure in most cases. A large number of cures which had been thus effected were incorporated with the paper.

#### THE HISTORY OF THE STETHOSCOPE, WITH THE PRESENTATION OF A MODIFICATION OF THE CAMMANN STETHOSCOPE.

By D. M. CAMMANN, M. D., of New York.

After giving the history of the stethoscope and describing Cammann's, the author exhibited his modification of the latter, which consisted in a rubber bulb attached near the rim of the chest-piece, and which when compressed, like the bulb of a syringe, and placed against the chest, exhausted the atmosphere and caused the rim to adhere firmly. The modification increased the intensity of the sounds conveyed to the ear, and allowed of the free use of both hands, which was of special advantage in auscultatory percussion.

The paper was discussed by Drs. TYNDALE, PLATT, HUDSON, The PRESIDENT, and the discussion was closed by DR. CAMMANN.

#### ELECTION OF OFFICERS AND NOMINATION OF COMMITTEES.

The PRESIDENT announced the election of the following officers:—

President, Dr. William Pepper, of Philadelphia; Vice-president, Dr. Frank Donaldson, of Baltimore; Second Vice-president, Dr. Beverley Robinson, of New York; Secretary and Treasurer, Dr. J. B. Walker, of Philadelphia; Council: Drs. Wilson and Hudson, of Philadelphia, Tyndale, and Bosworth.

The PRESIDENT appointed the following committees:—

Committee on Sanitaria, to interest benevolent persons in the establishment of sanatoria at suitable health resorts: Dr. N. C. van Bibber, chairman, of Baltimore; Dr. E. L. Medean, of Saranac Lake, New York; Dr. Boardman Reed, of Atlantic City; Dr. Charles Denison, of Denver, Colorado; Dr. H. A. Johnson, of Chicago.

Committee on Mineral Springs: Chairman, Dr. Cable, of Charlotteville, Florida; Dr. William Osler, of Philadelphia; Dr. Gebhart, of Hot Springs; Dr. Burchard, of New York; Dr. D. E. Borger, of Park Robles Springs, Colorado.

Committee on Health Resorts and Collective Investigations from the Various Health Resorts, on recommendation of the local physician or physicians at each place to the Association: Dr. F. C. Shattuck, of Boston, chairman; Dr. A. N. Bell, of Brooklyn; Dr. A. Y. P. Garnett, of Washington; Dr. H. V. M. Miller, of Atlanta, Georgia; Dr. E. L. Shurley, of Detroit, Michigan.

The PRESIDENT then announced a reception at the University Club Theatre, given by the New York members of the Association to the non-resident members, after which the Association adjourned.

#### NEW YORK COUNTY MEDICAL ASSOCIATION.

STATED meeting, held at the Carnegie Laboratory, May 18, 1885.

#### THE ADVANCE IN OUR KNOWLEDGE OF THE ETIOLOGY OF DISEASE.

The principal paper of the evening was by Dr. E. G. JANEWAY, on the above subject. In this country, he said, no greater inducement to study existed than that innate desire for knowledge which could best be compared to the hunger for food which seizes upon the starving; but oftentimes those well adapted for original investigation had been absolutely unable to succeed for the want of the necessary means, appliances, and place for such work. Moreover, any one here, unless possessing a private fortune, had to give up a large share of his time and thought to acquiring the means of a livelihood and for the apparatus and other expenses incident to his work. This had to be done either by teaching or practice, and he was thus subject to constant interruptions, and was obliged to work at scientific subjects, not when fresh and vigorous, but when weary and jaded, and hitherto too often in places little adapted to encourage work under such disadvantages. But, thanks to the liberality of the gentleman by whose name this building in which the Association had met was called, one of the great obstacles to successful labor of this kind had been overcome. That it was admirably adapted for the purpose he thought all would admit.

The history of medicine until within the last forty years had contained much that had been grossly theoretical, when the subject of to-night's thought was considered. He did not mean to deny that there were those who had the foresight to see through the dim mists on the horizon the rays of the sun of knowledge that were later to flood the scientific world with glorious light; but they lacked the means and appliances to prove the correctness of their surmises. Rudolph Virchow was a name which would long continue to be honored by all students of medicine. He had been chief among those who had led in the paths which have developed our present methods of investigation, and in his pupils scattered throughout not only Germany, but the world, a corps of workers was seen which had brought, and would still continue to bring, order out of chaos. Jenner was usually considered only in the light of a benefactor to the human race because of his success in preventing the spread of smallpox by the introduction of vaccination. Yet this operation, while primarily of so great value in this respect, had had a secondary influence in suggesting that for other diseases some such method might be employed, and thus leaving inquiring minds to search for the true cause of these diseases.

The origin of the idea that a number of diseases called infective spring from organisms which have entered from without and grow and multiply in the body, to again infect others, had probably sprung in most minds from the established instances of parasitic development as witnessed on the skin and in the interior. To Schwann we owed the idea that putrefaction and fermentation were dependent on the presence of germs or vegetable organisms; and to

Pasteur the dogmas that without such organisms there is no fermentation or putrefaction, and that for the different kinds there exist specific varieties, as well as the idea and method of endeavoring to separate the different varieties by fractional culture. After the acceptance of the belief that fermentation and putrefaction were dependent upon germs which rapidly multiplied under favorable conditions, the search after the organisms productive of infectious diseases could not be long delayed, nor the idea, which many already entertained, that in all of these disorders there must be a specific infecting agent which we might obtain for further research, be hindered from obtaining more adherents. The proof of such ideas in an absolutely satisfactory manner was of extreme difficulty, and as yet had been accomplished but for a few of the disorders; but Dr. Janeway did not doubt that the time would come when we should witness each of the disease-exciting germs classified and its life history known. The nature of the proof demanded was as follows:—

(1) The disease-exciting germ must be found constantly present during the existence of the disease, or at least of its earlier stages.

(2) It must admit of cultivation out of the body under such circumstances as to assure us of its purity.

(3) Reintroduced into the system it must excite in susceptible individuals the same disease phenomena.

(1) In the individual so made ill by the introduction of the culture we must again find the same germs as the cause. He did not here consider the question as to whether the symptoms were due to the irritation produced by the presence of the germ, or to chemical products produced by the nutrition of the germ and the effete products left over from such process.

Many observers had noted the presence of micrococci, bacteria, and the like, before the sure proof was afforded that any one of these diseases in man or animals was dependent upon a specific germ. The fact of their presence in connection with a given disease had invariably been met by those who did not accept them as the cause by the statement that the found a favorable soil which had been produced as a means of the previously existing disease in which they could multiply. Hence, experiments by inoculation of animals by diseased masses or by the blood containing the distinct evidences of bacilli did not produce an acceptance of the theory that the disease was due to a specific germ.

Dr. Janeway then took up successively the results which had been obtained in the study of the aetiology of splenic fever, relapsing fever, inflammations (such as abscesses, erysipelas, pyæmia, osteomyelitis, etc.), and pneumonia. In regard to pneumonia he said that patient and continued research had enabled the recognition of micrococci. These could be found in the sputa, and Leyden had obtained them in the fluid drawn from the lung by hypodermic puncture during life. It was claimed that after cultivation they might be inoculated with success in the lungs of mice. Whether these micrococci are the ultimate cause of the disease it might take a long time to determine; but of their actual occurrence he had

assured himself. In one instance recently, four Italians living in the same shanty at Tarrytown, N. Y., had sickened with pneumonia, and at the autopsy of one of these, four hours after death, the speaker was able to find in the red hepatization, and particularly in the pleural exudation and lymphvessels of the plenum, numerous micrococci, as cocci and diplococci, and also in somewhat longer chains of complets. Dr. George T. Harrison had related to him the instance of the widow of a physician who was the fourth of a series of individuals in the same house taken with the disease. During the past winter he had seen in the country a farmer ill with pneumonia whose wife had died of the disease some months before, and the man who went for the doctor the night he was taken ill was also seized with pneumonia.

Having spoken of the presence of micrococci in variola, vaccinia, scarlet fever, diphtheria, gonorrhœa, and endocarditis, he said that the result of Koch's researches upon tubercle and cholera were familiar to all.

Later, Dr. Briggs, who had recently returned from Berlin, showed cultures of the thin comma-bacilli, as they are called: the mouth-comma, that of cholera nostras, and that of Asiatic cholera. Shortly before he left Germany, Professor Müller had been able to grow the mouth-comma separate from associated forms, and thus study its life history.

In numerous cases of typhoid fever a bacillus had been found, not alone in the intestine, where it was commingled with numerous others of different sorts, but also in the mesenteric glands and in the spleen. In five cases of the disease in which he had himself made autopsies last fall it was present in each, corresponding in character with the description given by Eberth and confirmed by Koch. No deductions of any value could be drawn from these instances, however, since, with one exception, the autopsies were made twelve or more hours after death. The bacilli of typhoid had been found capable of growth upon culture-fluids, but it would be difficult in this way to prove the disease, as the germs would necessarily have to be fed to people susceptible to typhoid fever and not exposed to its influence. For typhus exanthematicus there are no known experiments as regards culture or demonstrations of the peculiar exciting agent. Dr. Janeway had examined the blood taken from a spot of skin the site of petechial rash, and had found in the fluids a few micrococci separate. It was a disease in which careful and repeated examination and culture might be able to demonstrate, as of the others, a specific agent. Leprosy had been found to contain a specific germ or bacillus somewhat resembling the tubercle bacillus in its reactions. Bacilli had also been found in glands which were capable of cultivation and of reintroduction into the system of a horse with effect of reproducing the disease.

The subject of the connection of organisms with disease, Dr. Janeway said in conclusion, was a large one and growing constantly. Robert Koch had proved himself the most thorough and reliable of those who had undertaken this study, and was now devoting all his energies, with a large corps of trained assistants, to the prosecution of the research in different directions. The knowledge which had

been gained would not simply be for scientific accuracy, but would avail much in our subsequent efforts to cope with disease. Nothing was more essential to a correct prophylaxis than a true etiology. He said he had omitted from the paper the discussion of sepsin and its congeners, ptomaines, chemical substances produced either by the action of bacterial changes or in the process of decomposition, which, according to some, are more responsible for the injury than bacteria.

At the conclusion of his paper Dr. Janeway presented

SPECIMENS OF ULCERATIVE ENDOCARDITIS AND OF  
ABSCESS OF THE LIVER.

In the patient suffering from the latter disease, which was apparently of traumatic origin, a number of aspirations were practised and a large quantity of chocolate-colored fluid drawn off. Afterward an incision was also made. Death resulted from exhaustion, and during the latter part of life there was noticed some dulness over the upper part of the right lung, with bronchial breathing. At the autopsy there was found waxy degeneration of the liver, with some peripheral fatty degeneration also. There was an enormous abscess of the right lobe, the walls of which were extremely firm on account of the waxy character of the hepatic tissue. There was also found periesophageal and peritracheal supuration, together with localized empyema in the upper lobe of the right lung and extensive ulceration of the large intestine. Dr. Janeway remarked that there were two sets of cases in which intestinal ulceration was found in connection with abscess of the liver. In the first, the cause of the trouble was dysentery, or other similar disease; but when this was the case there were generally multiple, though small, hepatic abscesses. In the second, as in the present instance, he believed that the ulceration of the large intestine was consecutive, and probably dependent on the depressed state of the general health and the presence of a septic process in the system. The condition was analogous to that met with in puerperal fever.

Dr. H. M. Briggs then gave a

DEMONSTRATION OF THE THIN COMMA BACILLI.

In the course of his remarks he stated that similarity of morphological appearances did not constitute identity. Identity of growth, culture, and function were essential to constitute this; and because this fact was not recognized by the recent English cholera commission their work was practically without value. Still the etiological relation between Koch's comma bacillus and Asiatic cholera, although even Klein had admitted that he had found the organism in greater or less quantity in all cases of the disease, could not as yet be regarded as positively proved. There was one point still lacking, namely, the test of inoculation, and it was quite possible that this never would be established, since, as far as could be determined, there was probably no animal that was susceptible to cholera. The so-called inoculation of guinea-pigs by means of injections into the duodenum was entirely unsatisfactory, and could not be accepted.

A demonstration was made of a

NEW CLOSED CIRCUIT "CURT BATTERY" AND INCANDESCENT LAMP, WITH UNIVERSAL ILLUMINATORS FOR DARK CAVITIES;

also the combined electric light and tongue depressor for laryngoscopic examinations, together with improvements on the Grenet battery. Some introductory remarks were made by the President, Dr. CHARLES A. LEAH, who said that recently in the examination of one of the dark cavities of the body he had used for illuminating purposes the small incandescent electric lamp, and that it had proved so satisfactory and combined so many recent improvements that he had deemed it worthy of a special notice and of presentation before the Association. The universal illuminator was an electric lamp attached by a ball and socket joint either to a long or a short handle, not much thicker than an ordinary penholder; being so small that it might be passed through an opening in the thorax, after the collapse of the lung and removal of the pus in empyema, to illuminate all the surrounding parts. It might be used in the rectum or the vagina, and also after gastrotony and cystotomy in searching for localized disease or a hidden foreign substance. In the abdominal cavity it might be utilized in seeking for the source of a concealed hemorrhage or for an injury to a fixed and obscure part.

For the mouth, throat, nares, and larynx, a combined tongue depressor had been attached, which was easily held in the left hand, while the right was free to manipulate. The improvements on the "Curt Battery" were the gain in space by the use of square jars, the employment of hard-rubber caps, replacing those of metal, and the increase of the exposed surface by the use of corrugated carbons.

MEDICAL SOCIETY OF THE STATE OF  
PENNSYLVANIA.

The thirty-sixth annual session of the Pennsylvania State Society, was held at Scranton, from May 27th to 29th inclusive. During the meeting the final passage of the bill to create a State Board of Health by the Legislature was announced; what the Society had failed to obtain by moral suasion though its Standing Committee had been made an actuality by the hard logic of the recent typhoid outbreak at Plymouth. The Society passed a resolution, after considerable discussion, which was proposed by the Committee on Medical Education, advocating the passage of a bill creating a special board to examine and license persons who wish to practise medicine in this State. These resolutions recommended that the sole power of granting a license to practice in Pennsylvania be vested in a single Board which should have no connection with any corporation engaged in medical teaching, the proceedings of the Board to be a matter of record open to public inspection, and that the medical profession should nominate to the Governor of the State a list of persons qualified to perform the duties of the board, from which he shall appoint the required number. It was furthermore recommended that a committee be appointed to prepare, in accordance with the views of the association, a bill to be

presented to the next Legislature, incorporating the above provisions. After considerable discussion the resolutions were adopted.

The Lackawanna County Medical Society presented a communication with regard to an irregularity in the practical application of the Registration act. It concerned a practitioner of medicine, of Scranton, who obtained a medical diploma from a Western college after an absence from home of less than two months. A protest had been made by this Society against the acceptance of this diploma, and the regular colleges in Philadelphia refused to endorse it, as the law requires, for registration. The holder of the diploma then went to the dean of the Homeopathic College in Philadelphia, who indorsed it, and he accordingly registered.

The Society, after considerable discussion, adopted a resolution offered by Dr. P. D. Keyser, declaring it to be the sense of the Society that diplomas granted in other States should be indorsed by colleges of similar kind in this State, thus requiring homeopathic colleges to confine their authorization to homeopathic diplomas. Referring to the recent attempt to have the Philadelphia County Medical Society memorialize the Legislature on the Medical Examiner Bill, the State Society adopted a resolution, on motion of Dr. H. H. Smith, declaring that all County Medical Societies which shall, without giving notice to the State Society, attempt to have legislation effected on any question shall be deemed guilty of contempt, and shall forfeit the rights they enjoy in the State Society until such disabilities be removed.

Among the papers read before the Society, the one which excited the most interest was one by Dr. Taylor, of Wilkesbarre, who presented a careful study of the outbreak of typhoid fever at Plymouth, tracing the epidemic to accidental contamination of the drinking-water with typhoid excreta. Drs. French and Shakespeare, of Philadelphia, also presented a report of their investigations, including post-mortem examinations, which proved the identity of the disease.

Dr. HENRY H. SMITH, of Philadelphia, read a paper on

#### THE NON-CONTAGIOUSNESS OF CHOLERA ASIATICA,

in which he opposed the views of Ferrán and Koch, and defended sanitary measures, disinfectants, and the use of ordinary precautions against an epidemic; he denied that there was any special danger to communities and individuals who observed the laws of hygiene.

Dr. S. S. Shultz, of Danville, read the address on "Mental Disorders"; Dr. J. G. Richardson, of Philadelphia, the address on "Hygiene and State Medicine"; Dr. Charles S. Turnbull, that on "Otolaryngology"; Dr. E. T. Bruen, that on "Medicine"; Dr. C. A. Rahter, of Harrisburg, that on "Obstetrics"; Dr. E. A. Wood, of Pittsburg, that on "Surgery"; and the annual address of the President was delivered by Dr. E. P. Allen, of Bradford County.

Among the volunteer papers read which especially deserve mention were: "Dermatitis Medicamentosa," by A. van Harlingen, M.D.; "A New Treatment of the Alcohol Habit," by William F.

Waugh, M.D.; "Nil Desperandum in Spinal Caries," by Benjamin Lee, M.D.; "Electric Light in Diagnosis," by Addmell Henson, M.D.; "Medicated Soaps for Skin Diseases," by J. V. Shoemaker, M.D.; "Osteotomy for the Correction of Deformities in the Lower Extremities," by H. R. Wharton, M.D., and "Dislocation of the Shoulder," by Oscar H. Allis. The officers elected for the succeeding year are: E. A. Wood, M.D., of Pittsburg, President; Hiram McGowen, Dauphin County; E. J. Russ, Elk County; A. H. Shaefer, Juniata County; C. C. Halsey, Susquehanna County, Vice-presidents; William B. Atkinson, of Philadelphia, Permanent Secretary; G. D. Nutt, of Lycoming County, Recording Secretary; J. H. Musser, of Philadelphia, Corresponding Secretary; Benjamin Lee, of Philadelphia, Treasurer. Williamsport was selected as the next place of meeting, on the first Wednesday in June, 1886.

### Recent Literature.

*Die Verdauungskrankheiten der Kinder.* Von D. ADOLF BAGINSKY, Privatdocent der Kinderheilkunde an der Universität Berlin. Mit 3 Tafeln Mikroskopischer Abbildungen. Tübingen: Verlag der H. Laupp'schen Buchhandlung, 1884.

In this interesting and valuable treatise Dr. Baginsky gives the results of his study during the past ten years on the digestive apparatus of children, which he has undertaken on a pathological basis and has illustrated with a number of microscopic plates. The work includes exhaustive articles on gastro-intestinal dyspepsia, cholera infantum, enteritis follicularis, the secondary, acute, subacute, and chronic gastro-intestinal catarrh, and the atrophy of children.

Besides commending themselves from their evident thoroughness and excellent method of arrangement, the various articles carry additional weight from the fact of the author's having already established himself as an authority by his monograph on "Pleurisy and Pneumonia" and his textbook on "Diseases of Children."

*The Care of Infants: A Manual for Mothers and Nurses.* By SOPHIA JEX-BLAKE, M.D., Member of the Irish College of Physicians; Lecturer on Hygiene at the London School of Medicine for Women; Attending Medical Officer at the Edinburgh Provident Dispensary for Women and Children. "Prevention is better than cure." London: Macmillan & Co. 1881.

This is one of the best little books of general advice for mothers and nurses which has yet appeared, in that it does not attempt too much, nor endeavor to tell the readers, for whom by its title it is indicated, what they cannot fully understand, and in not understanding do harm in their attempts to follow, a very common fault in treatises of this class.

As in all manuals on this subject, it would have been better if the authoress had contented herself with a general warning against artificial foods, and not attempted to explain when or how they are to be used, a subject which is entirely beyond the understanding of mothers and nurses.

**Medical and Surgical Journal.**

THURSDAY, JUNE 11, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by CUPPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM AND COMPANY,

283 WASHINGTON STREET, BOSTON, MASS.

**ANNUAL MEDICAL MEETINGS.**

THE season of the year devoted to the meetings of State Medical Societies and National Associations in special departments of medical science is again upon us.

Pennsylvania, Ohio, Illinois have already had their annual reunions within the last two weeks. This week Massachusetts, Rhode Island, and Maine hold their meetings, too simultaneously for those who would like to attend more than one of them. Next week the New Hampshire Society holds its meeting. Of the National Associations the Climatological met in New York two weeks ago, the Neurological Association meets in New York next week, the Laryngological will meet in Detroit about the same time, the Ophthalmological and Otolological at New London in the middle of July, the Dermatological at St. Louis in August, the Gynecological at Washington in September.

Here are ample opportunities for the cultivation of friendly relations between professional brothers for the exchange of views and a comparison of results.—opportunities which the nature of the practising physician's calling make especially desirable and should make especially profitable for him.

**CONGENITAL DISPLACEMENT OF THE HIP.**

IN our last issue we published the detailed account of the reduction of a double congenital luxation of the hip by Dr. Buckminster Brown, of Boston. In the case recorded by Dr. Brown, the patient, untiring, and ingenious efforts on his part as surgeon accomplished the reduction of the dislocation, which has remained reduced ever since.

Notoriously unamenable to treatment as this condition has been considered, it will perhaps be not amiss to hastily review the usual means for dealing with this deformity. The subject naturally divides itself into the operative and mechanical methods of treatment.

E. Rose, in 1871, ventured to resort the head of the femur in a unilateral congenital dislocation.

C. Regher soon followed with two resections for single congenital dislocations. Margary<sup>1</sup> reports seven excisions of the head of the femur for this deformity. The joint was exposed by a straight incision extending from the posterior superior spinous process of the ilium to the great trochanter, the thigh being adducted and flexed. The joint being freely opened, the round ligament divided and the soft parts protected, the head of the femur was severed by an Adam's saw. All this under anti-septic precautions. Extension was immediately applied and continued throughout the treatment. Two cases were decidedly benefited; the results in the others were not recorded.

The great obstacle to all attempts at a reduction of this deformity is the obliteration of the true acetabulum. To obviate this difficulty Heusner,<sup>2</sup> in the case of a girl twenty years of age where there was great pain, not only excised the hip-joint but deepened the acetabulum by chiseling; and Margary, in another case, after opening the hip-joint chiseled out the acetabulum. The deformity in these cases was reduced and the capsular ligament was reinforced by a strip of periosteum removed from the posterior superior margin of the acetabulum. Heusner's case was relieved of pain and could walk at the end of three months. Margary's case died of septicæmia.

Finally, as representing another operative method, we have Broadhurst's free division of all opposing muscles about the hip-joint.

The mechanical treatment of this deformity has been attempted by the various extension-splints. Certainly Dr. Brown's case is valuable and very striking as an exponent of what can be accomplished by properly adapted mechanical contrivances and the careful, minute supervision of a competent orthopaedist.

Dr. Brown is to be congratulated upon his success; comparatively few surgeons would be capable of that unremitting attention to details which characterizes the treatment of this patient.

We feel that he strikes the keynote of the mechanical treatment of the deformity when he says: "The apparatus used was designed as the objects to be accomplished and the exigencies of the treatment presented themselves." The recognition of this principle of mechanical treatment has, in a large measure, given him success.

Our drift, at present, is toward brilliant operative methods. Dr. Brown has demonstrated that certain cases can be safely and successfully treated by mechanical procedures alone.

— Dr. Edward Cowles, Superintendent of the McLean Insane Asylum, at Somerville, Mass., is to give a course of lectures on Mental Diseases at the Dartmouth Medical College next autumn.

## THE INFLUENCE OF SEA-VOYAGING UPON THE GENITO-UTERINE FUNCTIONS.

AN interesting and suggestive paper was recently read before the New York Academy of Medicine on this important subject by Dr. J. A. Irwin, of New York, who has had much medical experience at sea. Had space permitted we should have been glad to have given our readers this article in full, but desire at least to bring to their notice the principal points developed by the writer. It is a timely contribution at this season when so many cross the Atlantic for a summer in Europe.

It is well known that the genito-uterine functions are liable to serious disturbances not only during a sea-voyage, but subsequently to it and presumably in consequence of it. The amenorrhœa of recent immigrants has long ceased to be a novelty, and yet we have never seen the phenomenon satisfactorily explained. The increasing frequency of ocean travel, however, renders it peculiarly important that the effects of sea-voyaging on menstruation, gestation, parturition, and lactation should be well understood: it is desirable, too, that the therapeutic possibilities of sea-life in the treatment of uterine disease should be more definitely known. Dr. Irwin's paper is therefore timely in more ways than one; and it is to be hoped that others, who like the author have had, or may have, extended opportunities for observation, will continue the investigation of the subject. We do not propose in this notice to examine in detail the statistics of the author, but rather to give the general results and conclusions at which he has arrived in his very considerable experience at sea.

The special agencies which might naturally be supposed to affect the female economy in an ocean voyage are classed by the author under three headings—psychical, aerial, and motional. Strong mental impressions, particularly fear, are well known to have a marked effect on the uterus, as well as on the stomach, intestines, and bladder: the sudden arrest of menstruation, which occasionally takes place at the time of embarkation, may fairly be attributed to fear in some cases. Again, sea-air has long been thought to have some mysterious power on the human economy: menstrual irregularities are of common occurrence during a summer residence at the sea-shore; but the same phenomena have been observed to follow a sojourn in the mountains, and while sea-air has an undoubted hygienic effect in many cases, its influence in the causation of functional disturbances is as yet undetermined.

The effect on the human body of the motion of a ship at sea has been carefully studied: sea-sickness is now considered by many, if not most, authorities as synonymous with motion-sickness; and the author believes that to the effects of motion the various phenomena of perverted uterine function are chiefly due. The constant tendency of this

motion, he points out, is “to determine an increased blood supply to the pelvic organs”; and the result differs in degree from a slight circulatory stimulus, which in many cases has a positive therapeutic value, to a decided vascular engorgement, with the various consequences of pelvic congestion. From the author's observations it appears that menstruation may be disturbed as to its regularity, duration, amount of excretion, and increase of pain or discomfort, according to the individual constitutional tendencies, the length of the voyage, condition of the weather, and the relation of the last period to the time of embarkation. As Dr. Forlyce Barker has already pointed out in his essay on sea-sickness, “when the voyage is begun near an approaching period, the flow is brought on two or three days earlier, and is more abundant than usual”: the author finds also, and is supported by the experience of many other ship-surgeons, that a premature return of the catamenia may occur at any time during the inter-menstrual period, but especially so when the voyage has been begun during the first ten days after a normal period on shore.

The amenorrhœa so often observed for two or three periods subsequent to an ocean-voyage is attributed by the author to the reflex disturbance of the uterus and ovaries caused by the nervous exaltation and pelvic hyperemia during the voyage; that is, the primary stimulus is followed by depressed innervation and pelvic anemia with consequent diminution or complete suppression of the flow at the next regular period. As to the amount of pain experienced during menstruation at sea, the author finds that in some women dysmenorrhœa is suffered for the first time in an ocean-voyage; and that the pain is intensified in all cases in which dysmenorrhœa is habitual on land, except perhaps in some cases of spasmodic or neuralgic dysmenorrhœa supposed to be dependent on anemia.

Regarding an ocean-voyage as a powerful emmenagogue, therefore, the author considers it a therapeutic agent of great value in the treatment of conditions included under the term chloro-anemia: “in amenorrhœa dependent on deficient tone, or an undeveloped state of organs; in retarded sexual maturity; in certain forms of leucorrhœa, uterine asthenia, and sterility; and above all in those delicate, gawky, over-schooled girls in whom abeyance of the uterine function is often among the first warnings of approaching phthisis.”

The effect of sea-voyaging on the course of gestation is a subject of great practical importance. It would seem that abortion should be of frequent occurrence at sea, if uterine congestion can justly be considered a cause of abortion; but the author's observation leads him to believe that however active may be the ganglionic and sympathetic influences of motion with its consequent pelvic congestion, sea-sickness and the visceral disturbances of violent and prolonged vomiting are the

main causes of abortion and premature labor in an ocean-voyage. He has noticed that at the seventh and eighth months violent sea-sickness almost invariably gives rise to pains, which, if unchecked, will usually go on to the expulsion of the fetus. During the early months he believes there is great danger of abortion, and advises that if a pregnant woman is to undertake a voyage at all, the safest time to be selected is during the fifth and sixth months.

It should be said that some authors do not accept these views, but think that abortion is an extremely rare consequence of sea-sickness; on the other hand, however, several ship-surgeons known to the author have seen many premature labors and abortions at sea, and believe sea-sickness to be the principal exciting cause.

#### MASSACHUSETTS HEALTH AGAIN A VICTIM TO LUNACY AND CHARITY.

THE conglomeration of Health, Lunacy, and Charity yoked under the Massachusetts Board of that name is again attracting attention by unsavory details of internal administration. These details, though no surprise to those familiar with certain reports and investigations of previous years touching one of the departments connected with the out-door poor, are just becoming known to the public at large.

We are sorry to have to refer at all to this dirty question. When, however, we see that the sanitary interests of the State are in danger of losing a valuable promoter and in fact their only competent representative upon this unwieldy Board, it is fit that the medical profession should know something of the causes which have led to such a danger.

Through the insistence of Dr. H. P. Walcott, who brought to a conclusion the equally disinterested but less successful efforts of several predecessors, one of the departments of the Board was compelled to purge itself. As a sequel, Dr. Walcott's name has not been presented in nomination for another term, his previous term having expired last Saturday. The name of the other member of the Board whose term expired at the same time, Mrs. Clara T. Leonard, was promptly sent to the Council three weeks since according to custom, so that she could be confirmed and take part in the reorganization of the Board for the ensuing year.

It is common talk that Dr. Walcott, under these circumstances, has refused to be considered as a candidate for reappointment. Whilst sympathizing with such a position, the only one consistent with a sense of self-respect, we cannot believe that Dr. Walcott would refuse to yield his personal preferences to the demands of those most competent to judge of the services rendered by him to the State in the past, and which are likely to be required in the

future of any one representing its sanitary interests at the State House, should those demands be heeded by the Governor.

We reserve all further comment upon the causes and consequences of this vacancy upon the Board, but desire to express our conviction—a conviction representing as we know that of a large number of our readers—that the State can ill afford to lose the assiduous, though gratuitous, services of such a man as Dr. Walcott or to treat him with indignity. Service in connection with this Board is not yet so sweet but that an exceptionally able, high-minded, and experienced man who is willing to work on it should be welcomed and encouraged; and if he can only carry good measures by voting with "bad" men, this is discreditable to the Board, not to him.

#### ON THE USE OF CONCENTRATED SOLUTIONS OF SALINE CATHARTICS IN DROPSY.

DR. MATTHEW HAY, in the *London Lancet* for April 21, 1883, proposed a novel method for the treatment of certain cases of dropsy, based on the administration of concentrated solutions of saline cathartics.

He there cites a case of cardiac dropsy where the patient seemed to be in the last extremity from suffering and prostration, dyspnoea, ascites, and general anasarca. "An abundance of soft râles all over the chest indicated a pronounced œdema of the lungs. He had taken every variety of renal and cardiac stimulants, and had been purged repeatedly." Dr. Hay ordered that he should have as little as possible of food and liquids during the night in order to free the alimentary canal from digestive juices and other fluids and permit the full action of the salt. The next morning three ounces of sulphate of magnesia were administered dissolved in two tablespoonfuls of hot water, no water to be given afterward.

The result was most gratifying. In less than an hour after the purgative had been given, its cathartic effect was manifested and there were repeated evacuations in the next few hours; on each occasion the water seemed to "gush" from him, and he passed unusually large quantities of urine. There evidently had not been merely a removal of so much fluid from the blood and tissues, as was necessary for the usual dilution of the salt within the intestines, but the sharp, sudden withdrawal of fluid from the tissues by the concentrated blood had initiated a movement of the fluid into the latter which had continued for some hours after the direct action of the salt and the blood had ceased and until the tissues were in great part rid of their superfluous liquid. The improvement was, in fact, most marked, and continued under an occasional repetition of the concentrated saline solution. The conditions of the treatment, then, are previous abstinence from food and drinks and the administration

of the salt (which should preferably be Epsom, on account of its great solubility) in a large dose in the smallest possible quantity of water.

Dr. W. G. Eggleston has reported in the *Journal of the American Medical Association*, March 28, 1885, the details of a case occurring in his own practice where the method of Dr. Hay was carried out with equally good results. The patient was suffering from a large pleuritic effusion, with prostration and gradually increasing dyspnea. Tapping was indicated and advised, but declined by the patient. He was then ordered to abstain from water and liquid food and to take, the next morning, sulphate of magnesia, three ounces in less than half a tumblerful of water. The salt operated in less than an hour, and during the day there were eight large watery evacuations. As the patient expressed it, the water literally poured from him. There was a marked decrease in the effusion. Another dose of the salt, three ounces, was ordered to be taken the next morning, and when seen the day following the fluid was still further diminished; this effect was now followed up by twenty drops of fluid extract of jaborandi, which produced copious perspiration. In three days more the fluid had almost entirely disappeared from the chest, the lung had resumed its functions, and there was no dyspnea. When last seen, several months after, there had been no return of the fluid. This new method of giving saline cathartics in dropsies merits farther trials by the profession.

#### MEDICAL NOTES.

—The Committee on Public Health of the Massachusetts Legislature have reported a bill to regulate the practice of medicine. As the bill is liable to undergo amendments, we defer publishing it in detail.

—The Boston School Committee has voted to establish the office of Instructor on Hygiene in the public schools of the city.

—In the notable Hoyt will case, as we learn from the *Medical Record*, Dr. Millard testified that Miss Hoyt had many imaginary ailments, among them a belief that she had diphtheria and that she had coagulated blood upon the brain. The doctor testified that to humor her he called a professional cupper and leecher, a man named Hansen, who conducted an employment agency for nurses. This man bled her a trifle behind the ear and then showed her a clot of blood on a plate, and she after that considered her head all right. "Did the nurse obtain the blood from her head?" General Butler asked. "He wasn't a nurse," answered the witness; "he only kept a nurse agency." "If he kept a nurse agency," returned the Massachusetts statesman, doggedly, "he was a nurse." "Then I

suppose if a man keep a stable, he's a horse," suggested Senator Evarts, wearily. "Or if he drive an ice-wagon, he's a cold in the head," murmured Mr. Root, sadly.

—A writer in the *Weekly Medical Review* reports a case of death from shock produced by the injection of a stream of cold water against the cervix of a pregnant woman, made for the purpose of inducing abortion. No post-mortem examination was made, so that the conclusion can hardly be considered as certain that the shock alone was the cause of death. The death must have been nearly instantaneous and there was evidence that no drug had been taken. The possibility of air embolism cannot of course be absolutely excluded, but that occurrence would be extremely improbable in the fifth month from a vaginal injection by a Davidson syringe, there being no evidence of cervical dilatation.

—The cholera in France seems to have been more benign in character among the military, than among the civil population. In seven army corps, from the last of June to the first of December, 282 soldiers were attacked, of whom 87 died; a mortality of twenty-five per cent.

#### NEW YORK.

—The closing exercises of the Long Island College Hospital were held at the Academy of Music, Brooklyn, June 3d. The graduates numbered forty-seven, and the address to the class was delivered by Mr. St. Clair McElwain, of the Board of Regents.

—The trustees of Columbia College have decided to add a course of sanitary engineering in the School of Mines, and the chair will be filled by Dr. J. S. Billings, U.S.A., who will also continue to lecture on hygiene. The degree of sanitary engineer will be granted to those who take the course for four years and pass satisfactory examinations.

—The fire department has very sensibly offered a number of engines for the purpose of flushing the streets and gutters in the vicinity of the rivers with salt water, and in accepting the offer General Shaler, President of the Board of Health, remarked: "I wish that we could avail ourselves of the opportunity now presented to adopt a scheme for the permanent use of salt water for sanitary purposes. It would cost little to lay a six-inch iron pipe from the rivers to the tenement-house districts with hydrants at convenient points. The powerful engines of the fire department could be used to force water into the pipe, and the street-cleaning department could attach short lines of hose and flush all the streets in the districts."

—The late Rev. D. H. Macurdy bequeathed \$5,000 to St. Luke's Hospital, and the late Peter C. Cornell, of Brooklyn, \$5,000 to the Brooklyn Hospital.

—The seventeenth annual commencement of the Women's Medical College of the New York Infirmary was held at the University Club Theatre, May 29th, when degrees were conferred upon eleven graduates, one of whom was from China. The address to the class was delivered by Dr. Edward H. Janes, of the health department. Professor of Hygiene, and among those present were the Chinese and Japanese Consuls.

—At the annual meeting of the State Board of Health, held in May, Dr. E. M. Moore, of Rochester, was reelected President, and all the former committees were reappointed.

—Several cases of smallpox have occurred among the passengers of the steamship Weser from Bremen, and of the Polynesia from Hamburg, both of which arrived at quarantine on the second of June.

—The bill providing for a Forestry Commission and the protection of the Adirondack woods, which was passed by the Legislature last month, has been signed by the Governor.

### Miscellany.

#### ARE THE DOCTOR'S HORSE AND BUGGY HIS TOOLS?

A PHYSICIAN in New Hampshire, when his horse and buggy were seized to satisfy the claims of his creditors, pleaded that as the "tools of his occupation" they were exempt from liability to seizure for debt, and under the statute replevined the articles. The following is the decision of the court under which the jury restored the property:—

"The court cannot say, as a matter of law, that a wagon or a harness is a tool of a physician's calling, and so exempt to all physicians; nor can they say it is not such a tool. The most that can be said, as a matter of law, is that it may be a tool of his profession if, in the particular case, it is reasonably necessary for him to use it as a tool. If it should appear that his practice was confined to his office, or that he was a physician or surgeon in a hospital, attending to no cases outside of the institution, or that he was a surgeon on shipboard, or that he went on foot or horseback, or on the ears, to visit his patients, a wagon and harness would not be exempt under our statute, because they would be of no use to him as tools in his practice. They might be of use to him in other respects, as in going to church, or carrying his children to school, or in visiting friends, or as a means of recreation and pleasure; but these uses are manifestly not within the legitimate scope of the technical duty of a physician. Not coming within the strict definition of the term tools, and not being reasonably necessary as tools for him in his practice of his profession, they would not be tools within the meaning of the statute, and so would not be exempt as such. But if it should be found that the physician claiming the exemption could not practise his profession with reasonable success without a team with which to visit his patients;

that he was located in a country town, for example, where it was necessary for him to ride a large part of the time in order to accomplish anything professionally, a wagon and harness might properly be found to be reasonably necessary for him as tools of his occupation. But the finding would be one of fact so far as the reasonableness of the use is concerned; and it could not be said that these articles are exempt to every physician, or to physicians generally, but only to the debtor in the particular case. If there is any doubt whether an article claimed to be exempt from attachment is a tool under the statute, the question should be submitted to the jury whether its use as a tool by the debtor in his business is reasonably necessary. If it is, it is exempt; otherwise, it is not exempt."

### JACKSONIAN EPILEPSY.

DR. WILLIAM OSLER, in the January number of *The American Journal of the Medical Sciences*, makes an interesting contribution to the pathology of a typical case of Jacksonian epilepsy. The case was that of a girl who died at the age of fifteen years and nine months, having manifested the epileptic phenomena for more than fourteen years. She had been healthy up to the age of sixteen months, when she had a fall on her head, though for five months after this no symptoms referable to the brain were noticed. From that date she became liable to attacks of spasms lasting for about seven months, and then disappearing for as long an interval; on one occasion she was free from them for a year. The spasms always began in the left hand, and after a time the leg became affected, the spasm beginning in the toes, the face being affected last. There was never any loss of consciousness, and in the intervals between the spasms the patient was quite well. Thus it is said that if a spasm happened to seize her whilst she was at dinner, she would get a pillow and place it on the floor, and then lie down until the spasm was over, when she would return to her dinner. When she was about eight years old, the left leg became weaker, and the foot began to turn in, and from that time contracture remained, but the arm was never in the least degree stiff. From the time she was eleven years old the fits became more frequent, and she was at one time unconscious for six weeks. For the last ten months of her life she was free from spasms. Her intellectual faculties were unimpaired throughout. Death took place during a paroxysm of convulsions. On examination of the brain a small firm glioma was found in the white substance immediately below the cortex, but hardly if at all invading the gray matter at the upper part of the ascending frontal convolution. The case affords, as Dr. Osler points out, confirmation of the view derived from Ferrier's experiments as to the seat of the leg-centre, and is quite in harmony with the pathological experiences of MM. Charcot and Pitres on this point. Dr. Osler was led to infer that the growth had always been small, and in the earlier stages of its development, though causing irritation enough to set up the convulsions, had not involved the white fibres coming from the leg-centre to such an extent as to produce the permanent contracture.

## Correspondence.

## PARIS LETTER.—MEDICAL MATTERS IN PARIS.

[FROM OUR SPECIAL CORRESPONDENT.]

PARIS, May 12, 1885.

One of the most valuable courses in Paris, and to the American medical student perhaps the most valuable of all (for we have nothing like it in copiousness of material and frequency of occurrence), is that at the morgue. If not a matriculate, the visitor cannot enter without a card of permission. This is obtained from the dean of, and at the medical school, or his secretary. He will at once ask for your diploma, which one rarely has in his pocket; next for a medical document of some nature proving your status.

If you really wish to attend the course it will not do to be embarrassed by these little matters, nor by the fact that your pocket is not filled with medical passports. You present your card as the only testimony in your immediate possession and politely beg the gentleman (who will say: "*Any one might present a card!*") to be good enough to believe you are a medical graduate, and finally his protests disappear under a smile, and he fills you a yellow card, numbered, bearing your name, your address, and good for one month. In return for his kindness you have only to enter in his register, your name, your country, your city, your age, where you were born and when, where you were graduated and when, and then write your name again as a sort of gentlemanly oath to the truth of the foregoing.

The course is called "*Conférences de Médecine-Légale Pratique*," and is held in a small amphitheatre in the morgue building, which admits perhaps fifty men, and at the hour is always full. There are three conferences weekly. Professor Brouardel conducts one of them; his two assistants the other two. There is, of course, always a body to be examined, death having occurred by violence, drowning, poison, or there has been a false diagnosis at the hospital where the death occurred. At all events the purpose of the autopsy is to discover the cause of death. In the case of a body drawn from the Seine, for example, the question to be decided is whether death occurred from drowning, or from violence before immersion, or whether the drowning was probably a suicide, etc. Every step has a medico-legal bearing. The most minute external and internal examination is made, and a careful record is kept. At the beginning of the autopsy, and as it advances, the student who holds the knife is questioned as to his opinion concerning the meaning of every abnormal sign, and if he fails to give a correct reply, or has no opinion to give, the audience is called upon for judgment. This creates the conference, and the professor and his assistants being very able the course is made unique in its great value to the students. Occasionally Brouardel does the entire work himself, thus converting the conference into a demonstration. The conference lasts one hour. I have seen Brouardel examine and pronounce upon three bodies within that period.

The manner of the necropsy is peculiar. The eyes are first incised and the lenses removed for examination. The body is next opened by means of a cut beginning at the bifurcation of the trachea, descending over the left costal cartilages and sweeping in a curve just inside the crest of the ilium, across above the pubes and back to the bifurcation by a similar path on the right side: an oval incision which lays open abdominal and thoracic cavities at once. The tissues are dissected away from below upward (the costal cartilages having first been cut through), and the sternum and tissues come away together. The organs are removed in the usual order, but a very much longer time is occupied in opening the intestines by the French,

than by the German, method. For purposes of examination longitudinal incisions are made, two inches apart, up each leg from ankle to hip, up each arm from wrist to shoulder, including the entire circumference of each limb, and also up the whole back from rump to shoulders and neck. This leaves the unfortunate cadaver in a state of mutilation which probably would not be permitted at home. Indeed, even Paris lay journals are complaining of what they consider unnecessary injury of bodies of people of the better classes who have met with violent death, and whose remains are subjected to legal post-mortem examinations.

The cranium is opened by two methods. By one the skull is quickly broken through in the usual circle with the sharp edge of a heavy steel hammer (shaped like that of a mason), and the brain is removed entire. The other method is to cut straight through the centre of skull and brain longitudinally, with a thin saw, from the middle of the os frontis to the occipital protuberance. Half the brain comes away with the top of the cranium. It seemed a very convenient cut. What was done with the remains of the bodies I did not learn. The organs, after examination, are thrown into a bucket and carried away.

At one conference, during which two stalwart male bodies were examined, there was present one young female student, quite near the table, and who talked and laughed with the men. It was not at all charming, but she did not appear in any way disturbed by her extraordinary surroundings.

A convenient use of water is managed by having the water-pipe come down from above, along the pipe of the gas-burners. The dependent hose is not in the way, cannot fall to the floor, and is always at hand.

It is easy to imagine the great usefulness of this course to students who attend the three weekly conferences. Every variety of medico-legal question in connection with autopsies is carefully discussed, and nothing is left undone to make each case clear in all its bearings.

During the recent Congress of French Surgeons, in proof of the occasional but rare preservation of the mobility of the leg and freedom from muscular atrophy after fracture of the patella, Larger introduced a man aged seventy-three, very robust, with no history of arthritis or scrofula, and no fracture of the patella among his ancestors or relatives. He has been four times the victim of this accident:—

(1) In 1846 transverse and median fracture of the right patella, treated by the Boyer apparatus.

(2) Patient recovered and resumed his occupation (butcher). Four months later the callus ruptured. A new recovery, without limp.

(3) In 1860 transverse and median fracture of left patella. Treated as before. Recovery, without limp.

(4) In 1862 occurred the final fracture of the right patella. Fracture transverse, but below the seat of the first and near the summit of the patella. Followed by persistent swelling of the knee. Puncture of the articulation gave issue to sero-sanguinolent fluid.

*Present condition anatomically:* Left patella divided into two parts by a fibro-callus four centimeters wide (fracture of 1860). On the right knee is a deep and ghastly sulcus at the habitual level of the patella, exposing very sharply the articular surface of the femur. The patella is no longer in contact with the surface of the condyles, but rests above upon the diaphysis. A callus one and one-half centimeters in width (fracture of 1846) joins the two rectangular fragments of the right patella. A third fragment, very small and triangular, formed by the summit of the patella, remains attached, at level of the head of the tibia, to the ligamentum patellæ. This third fragment is absolutely detached from the other two and has no connection with them, as may be proved by digital examination. Further, when the anterior muscles are contracted the patella ascends the thigh nearly to the junction of its

middle and lower thirds. Finally, the articulation of the two knees is perfectly normal.

**Functional power:** In spite of four fractures this man was able to continue his business. He has now retired, walks easily on a level without a cane and without limping, but slightly drags right leg. Goes upstairs without effort and more easily than any one of his age (73) in his neighborhood. Experiences only slight difficulty in descending, when he is obliged to stiffen one leg. Plays ten-pins; walks ten kilometers daily. Keeps pace with any one when he has a cane. Extension of the left leg upon the thigh perfect in spite of four centimeters of fibrous callus. In right leg, power of extension not nearly so perfect but exists, although the patella is entirely detached from the tibia. Duchenne, who saw a similar case, explained that extension was permitted by means of lateral fibrous attachments of the vastus, external and internal, to the superior and lateral surfaces of the tibia. In Larger's case the lateral fibrous bridges can be felt during extension. Finally, all of the inferior

extensor muscles are normal, the right triceps femoris alone having suffered a slight atrophy. The conclusion was that impotence of the leg after fracture of the patella depends only to a very slight degree upon the distance between the fragments. In fact, in this case the vasti, external and internal, which principally preside over extension of the leg are but slightly disturbed in their action. The true reason of functional impotence after such accidents is arthritis and muscular atrophy of the extensors. The reason, said Larger, that in this case four fractures of the patella have caused such slight functional loss of power is because articulations and muscles have remained intact.

For a very lengthy, interesting, and warm discussion on the treatment of this fracture, with especial reference to Lister's operation of osseous suture in recent cases, and for a long series of statistics, see the *Bulletin de la Société de Chirurgie*, 1883, séance of November 14th. Larger's patient was shown at that time, and I have used the discussion. It is a very rare and striking case. Yours very truly, n. o.

## REPORTED MORTALITY FOR THE WEEK ENDING MAY 30, 1885.

Deaths reported 2,238; under five years of age 719; principal infectious diseases (smallpox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhoeal diseases) 325; lung diseases 271; consumption 281; diphtheria and croup 98; diarrhoeal diseases 71; scarlet fever 39; measles 31; malarial fevers 25; typhoid fever 15; whooping-cough 12; erysipelas 11; puerperal fever 11; cerebro-spinal meningitis seven. From measles, New York 13, Brooklyn 11, Boston four, New Orleans, Nashville, and Cambridge one each. From malarial fevers, New York 10, New Orleans seven, Philadelphia and District of Columbia three each, Brooklyn two. From typhoid fever, Philadelphia five, New York and Providence three each, New

Orleans, Charleston, and Lowell one each. From whooping-cough, New York five, Philadelphia and Brooklyn two each, Boston, District of Columbia, and Cambridge one each. From erysipelas, New York five, Boston and New Orleans two each.

Cases reported in Boston: measles 75, scarlet fever 11, diphtheria 22, and typhoid fever five.

In 113 cities and towns of Massachusetts, with an estimated population of 1,063,073 (estimated population of the State 1,255,101), the total death-rate for the week was 15.43, against 18.19 and 17.52 for the two preceding weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,906,105, for the week ending May

16th, the total death-rate was 20.4. Deaths reported 3,487; infants under one year of age 800; acute diseases of the respiratory organs (London) 291, measles 143, whooping-cough 126, fever 45, scarlet fever 37, diphtheria 33, diarrhoea 39, smallpox (London) 45, Manchester four, Sunderland one) 50. The death-rates ranged from 10.9 in Brighton to 33.3 in Preston; Birmingham 17.9; Birkenhead 19.6; Bradford 16.8; Leeds 20.5; Leicester 18.8; Liverpool 24.8; London 19.1; Manchester 27.7; Nottingham 19.0; Sheffield 24.9; Sunderland 25.0. In Edinburgh 17.3; Dublin 35.0; Glasgow 20.4.

For the week ending May 16th in the Swiss towns there were 27 deaths from consumption, lung diseases 17, diarrhoeal diseases 13, diphtheria and croup seven, typhoid fever four, smallpox two, measles two, whooping-cough one.

The death-rates were: at Geneva 12.1; Zurich 7.8; Basle 18.9; Berne 28.4.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MAY 29, 1885, TO JUNE 5, 1885.

HORTON, S. M., major and surgeon. Ordered for duty as post surgeon, Fort Riley, Kansas.

CLEARY, P. J., A. M., major and surgeon. Ordered for duty as post surgeon, Fort Lyon, Colorado. S. O. 78, Department of Missouri, June 1, 1885.

BROWN, J. M., major and surgeon. Assigned to duty as post surgeon at Fort Omaha, Neb.

BRECHEMIN, LOUIS, captain and assistant surgeon. Relieved from duty at Fort Omaha, Neb., and assigned to duty as post surgeon at Fort D. A. Russell, Wyo. S. O. 49, Department of the Platte, May 29, 1885.

AINSWORTH, F. C., captain and assistant surgeon (Department of Texas). Ordered for temporary duty in Department of Missouri. S. O. 58, Department of Texas, May 25, 1885.

POKTER, JOS. Y., captain and assistant surgeon. Granted leave of absence for six months on account of disability. S. O. 126, A. G. O., June 3, 1885.

DAVIS, WILLIAM B., captain and assistant surgeon. Granted leave of absence for one month from May 25, 1885. S. O. 122, A. G. O., May 28, 1885.

ROBERTSON, R. L., first lieutenant and assistant surgeon. Leave of absence extended one month. S. O. 123, A. G. O., May 29, 1885.

#### SOCIETY NOTICES.

AMERICAN NEUROLOGICAL ASSOCIATION. — The eleventh annual meeting of the Association will be held in the hall of the Academy of Medicine, 12 West Thirty-first Street, New York, on June 17th, 18th, and 19th; afternoon and evening sessions. Members of the profession are cordially invited to attend the sessions of the Association.

Wednesday, June 17th. Afternoon session at 2.30 o'clock. Remarks by the President, Dr. Isaac OUI. Introduction, by the retiring President, of the Vice-president elect, Dr. Leonard Weber, of New York. Reports of Council, of Secretary, and Treasurer. Scientific communications: (1) Dr. E. C. Spitzka, of New York, "The relation between the symptoms and the Lesions of Posterior Spinal Sclerosis;" (2) Dr. J. T. Eskridge, of Philadelphia, "A case of Acute Ascending Paralysis (Landry's disease);" (3) Dr. A. D. Rockwell, of New York, "A case of Chronic Myelitis: recovery;" Evening session at 8.30 o'clock. Scientific communications: (4) Dr. George W. Jacoby, of New York, "On the use of Osmic Acid in Peripheral Neuralgias;" (5) Dr. E. C. Spitzka, of New York, "Clinical Observations on Spinal Irritation."

Thursday, June 18th. Afternoon session at 2.30 o'clock. Address by the President, Dr. B. G. Wilder, of Ithaca, N. Y., "Paronymy versus Heteronymy as Neurologic Principles." Scientific communications: (6) Dr. Charles K. Mills, of Philadelphia, "The Brain of a Delusional Monomaniac who killed several Persons;" (7) Dr. B. G. Wilder, of Ithaca, "On a seldom described Artery (A. terminalis), with suggestions as to the names of the principal Encephalic Arteries;" (8) Dr. B. G. Wilder, of Ithaca, "Exhibition of preparations illustrating (A) the form and extent of the adult aorta; (B) the non-extension of the rim to the tip of the medulla; (C) the enlargement, yet complete circumscription, of the porta in an aliopied hydropcephalus; (D) the fibrous revent and its relation to the prosencephalon; (E) the continuity of the diencephalic endym from the mesal surface of the thalamus over the lamina to the diaterle;" (F) the insula of the monkey, chimpanzee, and porpoise. There will be no evening session on this day.

Friday, June 19th. Afternoon session at 2.30 o'clock. Scientific communications: (9) Dr. E. C. Spitzka, of New York, "Demonstration of a Brain Monstrosity;" (10) Dr. B. G. Wilder, of Ithaca, "On two little-known cerebral Fissures, with suggestions as to fissural and gyrus names;" (11) Dr. Wharton Stalker, of Philadelphia, "Two cases of Friedreich's

Disease." Evening session at 8.30 o'clock. Scientific communications: (12) Dr. E. C. Spitzka, of New York, "The Anatomy and Physiology of the Tracts comprised under the name 'Lemniscus' or 'Fillet'." "The Anatomy of the Trineural Fasciculus;" (13) Dr. B. G. Wilder, of Ithaca, "Preliminary Report of the Committee on Encephalic Nomenclature;" (14) Dr. E. C. Seguin, of New York, "A Contribution to the Pathology of the Cerebellum." Other papers and cases.

SUFFOLK DISTRICT MEDICAL SOCIETY. SUMMER PRACTICE. — All members of the Suffolk District Medical Society may send to Dr. Edwin H. Brigham, Medical Library, 19 Boylston Place, the days and hours on which during the months of June, July, August, and September they will be in the city to receive patients, with their addresses. After this information is collected and available a notice to the public will be given through the *Advertiser and Transcript*.

DR. EDWARD WIGGLESWORTH.

DR. F. I. KNIGHT.

BOSTON MEDICAL LIBRARY ASSOCIATION, 19 Boylston Place.

#### DEATH.

In South Boston, June 5, 1885, Joseph Ferdinand Gould, M.D., M.M.S.S., aged fifty-five years, six months.

#### BOOKS AND PAMPHLETS RECEIVED.

Annual Report of the Secretary of the Navy for the Year 1884. In two Volumes. Volume II. Washington, 1884.

Revolution in the Practice of Medicine, by John Floyd Banton, M.D. Second Edition. Chicago, 1885.

Twenty-seventh Annual Report of the Washingtonian Home, located at 41 Waltham Street, Boston, 1885.

China, Imperial Maritime Customs, II. Special Series No. 2. Medical Reports for the Half-year ended March 31, 1884. Twenty-seventh Issue. Published by order of the Inspector-general of Customs, Shanghai, 1884.

Eighteenth Report of the Medical Staff of St. John's Hospital, Submitted April 6, 1885, Lowell, Mass.

Epilepsy, by L. W. Baker, M.D. Read before the New England Psychological Society, December 9, 1884.

On the Use of the Absolute Galvanometer, with Description of Hirschmann's New Instrument, by B. Sachs, M.D., New York. (Reprint from Journal of Nervous and Mental Diseases, Vol. XII., January, 1885.)

Ueber der Nutzen der Chromwasser-Behandlung in einem Falle von Syphilis maligna. Von Dr. J. Edmund Gintz in Dresden. Separat Abdruck aus Betz's Memorialien. 1885. 2 Heft.

Scarlet Fever and certain Suggestions for its Treatment. In accordance with the most recent advances in Science and Experience. By T. Griswold Comstock, M.A., M.D. (Reprint from New York Medical Times, March, 1885.)

Clinical Lectures, on Scrofulous Neck, by T. Clifford Allbutt, M.A., M.D., Cantab., F.R.S., F.R.C.P., Consulting Physician to the Leeds General Infirmary.

On the Surgery of Scrofulous Glands, by T. Priddin Teale, M.A., M.B., Oxon., F.R.C.S., Consulting Surgeon to the Leeds General Infirmary, London: J. & A. Churchill, 1885.

The Art of Massage, No. 1. Tracts on Massage, Translated from the German of Rehnauer, with Notes, by Benjamin Lee, A.M., M.D., etc., etc. Philadelphia, 1885.

Transactions of the New York State Medical Association for the year 1884. Vol. I. Edited for the Association by Austin Flint, Jr., M.D., New York: D. Appleton & Co., 1885.

Medico-Chirurgical Transactions, Published by the Royal Medical and Chirurgical Society of London. Second Series, Vol. XLIX. London: Longmans, Green & Co., 1884.

On the Significance of the Development of Optic Neuritis in Cases of Purulent Inflammation of the Middle Ear, by Charles J. Kipp, M.D., Newark, N. J. (Reprint from Archives of Otolaryngology, Vol. XIV., No. 1, 1885.)

Vorträge und Discussionen gehalten von dem Deutschen gesellig-Wissenschaften Verein von New York vom Juni, 1870, in April, 1885.

Insanity and Divorce. The Neuropathic Conditions and Treatment of Cancer, Myomania, by C. H. Hughes, St. Louis, Mo. (Abstracted from the Alienist and Neurologist, April, 1885.)

A Case of Psycho-Sensory (Affective or Moral) Insanity, by C. H. Hughes, M.D., St. Louis, Mo. (Reprint.)

How to Feed the Baby. A Lecture delivered before the Philadelphia Hospital Training School for Nurses, by J. M. Keating, M.D.

Medical Topics, Containing: (1) Hints and Suggestions for Reform in Medical Education, (2) A Plea for the State Regulation of Medicine and Surgery, (3) Medical Education: Its Objects and its Requirements, by F. E. Sturgis, M.D., New York: William Wood & Co., 1885.

## Lecture.

ANTISEPTIC SURGERY.<sup>1</sup>

THE ANNUAL DISCOURSE BEFORE THE MASSACHUSETTS MEDICAL SOCIETY, JUNE 10, 1885.

BY FRANKLIN K. PADDOCK, M.D., OF PITTSFIELD, MASS.

IN fulfilling the conditions of this method, the simple application of germicides only partially completes the requirements of antiseptic surgery. There are other causes of inflammation than bacteria, which, it is apparent, must be avoided. The observance of every measure which hastens complete recovery is included in this system of treatment.

The general health of the patient is one of the most important considerations in determining the prognosis and the result of a wound. Freedom from mental and arterial excitement should be secured, as well as perfect rest and comfortable posture for the wounded part. These and many other considerations, varying, of course, to meet the demands of special cases, must not be ignored in fulfilling the requirements of this method.

In the case of accidental wounds, wounds that have been freely exposed to the air are more or less inflamed, and frequently the seat of fermentation when first seen by the surgeon. The same general principles must be observed as in the treatment of wounds made by the surgeon's knife.

The primary object is to destroy all the bacteria and micrococci that are present; this is accomplished by making a thorough application of the lotion to every portion of the wound. Syringing and douching are important measures in rendering the germicide efficacious. The secondary object to accomplish is, by efficient external dressings, to prevent the access of new germs.

Most accidental wounds are of recent occurrence when first placed under the surgeon's care. These, after being well cleansed and rendered aseptic, can be closed by sutures, with a fair prospect of securing union by first intention. The value of absorbent drains and efficient antiseptic covering is particularly marked in this class of wounds. Union by second intention is frequently acquired in such when primary union has failed. To succeed in this, careful coaptation of the granulating surfaces must be made and complete protection from subsequent germinal invasion assured.

It is surprising how rapidly even large wounds of this sort usually heal when treated in this way. Wounds that require weeks of treatment by ordinary methods get well in as many days when fermentation is prevented. The effect of germ exclusion is to immediately diminish the amount of the discharge, and at the same time radically change its character; the pus becomes normal, and the necessity for frequent dressings is obviated.

The importance of furnishing an abundance of porous antiseptic material to envelop the wounded part, for the purpose of filtering the air and absorbing all discharge, should not be forgotten, for the efficiency of the treatment depends upon complete protection.

The antiseptic treatment of abscesses, both acute and chronic, involves the execution of the same gen-

eral details. Their contents should be evacuated in such a way as to prevent the access of air or germs to the abscess cavity. Thorough drainage should be established, employing, if necessary, rubber tubing, spun glass, or horsehair. The entrance or orifice should be well protected from infection by the antiseptic gauze or other equally efficient dressing. The results of similar treatment in the management of pleural and psoas abscesses show a decrease of fatality as compared with other methods.

The injection of abscess cavities is rarely necessary; in fact, the danger of the absorption of the antiseptic is so great, especially in large cavities, that it should generally be avoided.

The important part of the local treatment consists in preventing the access of germs to the cavity. It is quite evident that the discharges of suppurating wounds, as well as the pus of abscesses, constituting, as these substances do, such favorable conditions for the development of putrefactive germs, should be made to flow away as rapidly as possible. To facilitate the speedy removal of such, constant irrigation is often of great service, using some antiseptic solution for the irrigating fluid. In case of wounds or abscesses that furnish discharges so profuse that absorbent dressings fail to afford sufficient protection, this treatment proves very serviceable in excluding organisms. It also tends to prevent any accumulation for the germs to develop in.

The antiseptic water-bath, for treating wounds of the extremities, is a method employed by some foreign surgeons with excellent results. The injured limbs are immersed in water which has been impregnated with alcohol, tincture of benzoin, or some agent to prevent fermentation. The contact of the water relieves inflammation and favors rapid granulation. There is a class of wounds which, I should judge, would do very well with the water-bath treatment. I am not aware, however, that it is employed to any extent in this country.

The recognition of bacteria as the cause of putrefactive fermentation logically led to the search for, and the discovery of, agents inimical to septic organisms. There are many substances that will destroy these microscopic bodies, but only a few are applicable in the treatment of wounds, in consequence of their injurious effect upon animal tissue. The term antiseptics, in its restricted sense, therefore, only includes those agents which can be employed to check germ development without producing serious detrimental effect upon wounds. The specific virtues of the different remedies are somewhat varied. They all tend, however, toward the accomplishment of the same object when properly and intelligently employed. Some of them are vigorous germicides, and destroy rapidly both bacteria and micrococci. Others exert a fatal influence upon bacteria, leaving the spore and micrococci unaffected, to develop in their natural way. There are still others that render the different varieties of germs inactive and inert without devitalizing them. As soon, however, as the effect of the agent ceases they resume their active reproduction and pernicious influence.

The artificial cultivation of these organisms has been successfully accomplished by numerous investigators, and their behavior under the influence of the

<sup>1</sup> Concluded from p. 565.

various antiseptics carefully observed, so that the knowledge we possess of the protective properties of these remedies is the result of scientific research as well as the effect of experiments upon wounds.

The antiseptic which, from the inauguration of this treatment until of late, has been inseparably connected with the method is carbolic acid. The fact that it was first successfully employed in demonstrating the principles of the antiseptic system will always contribute to its notoriety, even if its virtues are excelled by some other agent. However, notwithstanding its defects, carbolic acid has not yet been displaced, although it does not at present maintain its former exclusive position in antiseptic surgery. The chief advantage is its universal applicability to all wounds as a germ destroyer, as well as its adaptability as a purifier to the hands and all materials used in an operation and about a denuded surface. Its disadvantages are that it is occasionally absorbed and produces poisoning; that when employed of sufficient strength to act vigorously as a germicide it excites local irritation in and about the wound; that its volatility renders necessary a more frequent change of dressings than is desirable. These objectionable qualities are magnified and exaggerated by the lack of skill and tact in its application. To avoid its toxic effects, the continued application of the acid to an extensive granulating surface should be interrupted and the strength of the solution used, carefully regulated.

Some constitutions are very sensitive to its influence, owing either to individual idiosyncrasy or to the existence of renal disease. Such are apt to feel the toxic effect of the drug, even when sparingly applied to a raw surface. Nevertheless, when the fact of its general employment during the last twenty years is considered, it is astonishing that comparatively so few cases of poisoning have been reported as a result of its antiseptic use.

Scarcely less can be said of the importance of corrosive sublimate as an antiseptic than of carbolic acid. It is certainly a more effective germicide. A very weak solution, one part to a thousand of water, immediately destroys both bacteria and micrococci, while a still milder solution, one part to five thousand, paralyzes, without devitalizing, them. Its application to the surface of wounds causes less irritation than carbolic acid. Its disadvantages are that it occasionally produces fatal poisoning by absorption; that the constant wetting of the skin in the vicinity of the wound not infrequently develops a troublesome eruption; that it tends to chemically combine the albumens in the discharge, forming a compound that is practically inert as an antiseptic; that its corrosive action upon metals militates it for the purpose of disinfecting surgical instruments.

Another very active germicide is the chloride of zinc, used in solution in water, in the proportion of one part to two to eight per cent. This agent is not applicable in the treatment of recent wounds, in which union by first intention is expected, because of its caustic effect upon the tissues. It is, however, exceedingly effective in destroying organisms in suppurating wounds, especially where septic material is abundant.

There is also a chemical action exerted by the agent upon the discharges, resulting in the formation of a film of zinc albuminate which covers the surface of the wound and constitutes an efficient protection so long as it remains. Zinc is not absorbed and its use is not attended with the danger of poisoning, although when the solution is too strong it may induce local inflammation and sloughing. It is not adapted for use as an external dressing; other agents are more efficient for this purpose.

There is one other antiseptic that I will speak of somewhat in detail, and that is iodoform. This has proved very effective as an external application in preventing the access of germs to suppurating surfaces. When applied too freely there is danger of absorption and iodoform poisoning. It is therefore kept from too intimate contact with the wound surface by using gauze or similar porous material as a medium of conveyance.

The dressing is prepared by rubbing or pressing finely pulverized iodoform into the meshes of any thin, loosely woven fabric like cheesecloth. The powder not admitted into the interstices of the mesh and there retained should be removed by gently shaking the cloth until the excess of the agent is disposed of. The resulting iodoform gauze constitutes not only a safe but one of the most valuable dressings for the protection of all kinds of wounds from infection. The gauze should be applied in layers to a sufficient depth and extent to absorb the entire discharge. It is a dry dressing and does not favor decomposition as the moist variety do.

The iodoform adheres to the gauze with sufficient tenacity to prevent enough of it from coming in contact with the absorbing surface to induce poisoning. Wounds that have been thoroughly cleansed and rendered aseptic by other agents can be maintained in a healthy condition with the protection afforded by this gauze for a considerable period.

The healing process in many instances is completed with one dressing, even when the wound is ragged, contused, and inflamed.

The progressive development of the principles involved in antiseptic surgery reveals the virtues as well as the deficiencies of the various antiseptic remedies. The search for one that is perfect is as yet unrewarded, although its vigorous prosecution has brought to the notice of the profession quite an array of drugs, possessing in a greater or less degree antiseptic properties.

The comparative merits of these different agents are gradually being demonstrated by many surgeons. Every year adds much to our knowledge of their general usefulness and their individual fitness for wounds and special purposes. Permanganate of potassa, iodine, bromine, salicylic acid, acetate of alumina, naphthalin, subnitrate of bismuth, and the oil of eucalyptus are some of the more prominent agents receiving attention at present.

In selecting and applying these remedies there are several rather important considerations to be borne in mind. Their indiscriminate and unintelligent employment, without reference to individual adaptation and effect, is apt to disappoint the expectation of the surgeon by results that are either

negative or injurious. (1) The nature and requirements of the lesion must be considered. Fresh, clean wounds require simply protection from the causes of inflammation. The chief of these is obviated by excluding the putrefactive germ with the external antiseptic dressing. Whereas suppurating wounds, in addition to, and precluding, protection require the extermination of the bodies that have gained admission to, and are multiplying in, the discharge. In accomplishing these different objects not unfrequently more than one remedy can be used with benefit in the treatment of the same lesion.

(2) The efficiency of the agent employed as a germicide should be considered. As a rule, the degree of putrefaction present determines the required strength or vigor of the antiseptic.

(3) The local effect of the agent upon the surface of the wound should be anticipated.

(4) The toxic influence of the drug, resulting from its possible absorption, should always be kept in view.

The majority of the germicides now in use produce injurious effects when introduced into the circulation in immoderate quantity. The danger of absorption depends in a measure upon the extent of surface exposed, as well as upon the length of the period of contact.

As the principles of the antiseptic method have become more distinctly defined the more fully is the fact recognized that the natural secretions form the most suitable fluid for bathing healing surfaces. When this is normal in character and amount the employment of antiseptic or other lotions to dilute or replace it is an uncalculated-for and injurious interference with nature. The aim and object of this method is to protect the normal secretions from the organisms which render them abnormal. The faithful and intelligent application of external protective dressings secures all the advantages that are to be derived from the use of antiseptic agents in the care of many wounds. Many of the cases of poisoning that have been reported can undoubtedly be reasonably attributed to their unadvised and too generous employment.

Some form of protection may be developed in the future which will enable us to dispense with drugs. At present, however, there is little or no light in this direction. In order to appreciate the great changes and the wonderful improvements in surgery since the introduction of the antiseptic treatment it is necessary to take a retrospective view of the results obtained previous to the last twenty years. That this improvement and progress in the surgical art is attributable to the discovery of the putrefactive germ, and the consequent development of the principles and methods comprised in the antiseptic treatment, no fair-minded person familiar with the facts can for a moment doubt.

Formerly the danger of gangrene, septicæmia, pyæmia, and erysipelas following operations and accidental wounds was appalling, and the operator was constantly oppressed with the nightmare of apprehension. The unfortunate complications attending suppuration and the process of healing by granulation induced surgeons to avail themselves of very radical measures to secure healing by first

intention. Many limbs were sacrificed by amputation in order to avoid the risks associated with the healing of inconsiderable wounds by granulation. Even this extreme course of treatment too frequently failed in securing immunity from the evils connected with suppuration. The surgery of twenty years ago was so different from the surgery of to-day that a comparison between the two is unsatisfactory, being rendered so by the great variety of operations that are now practicable which then were rarely undertaken.

The contrast in treatment and results is equally great. Formerly the mortality following major operations was about thirty per cent., the greater number of the fatal cases being the result of pyæmia or septicæmia. The present mortality after such operations is reduced to about five per cent., and septic poisoning is a rare occurrence, except in cases that are not properly protected by the antiseptic method.

Conservative surgery has progressed surprisingly since the elimination of septic poisoning from the list of probable dangers attending the healing of open wounds. The success of conservatism has naturally resulted in narrowing the field of heroic surgery, which is employed now with more caution than formerly. A comparison of the results of similar operations, as formerly conducted and as now treated with antiseptic protection, reveals in a marked degree the advantages of the new method. A list of five hundred and sixty-three amputations, reported by Malgaigne in 1842, including amputations of the thigh, leg, foot, shoulder-joint, humerus, and forearm, resulted in a mortality of three hundred, or over fifty-two per cent.

Paul, in 1851, gathered and reported a list of 5,060 amputations, including both upper and lower extremities, the mortality of which amounted to 1,997, or over thirty-nine per cent. These reports are fair illustrations of the results obtained with old methods of treatment.

Schäfer reports a list of 321 amputations, including both extremities, treated antiseptically, with a mortality of less than five per cent.

Volkman reports 139 similar amputations receiving also antiseptic treatment, with a mortality of less than four per cent.

I am conscious of the unreliability of such statistics as these in demonstrating accurately the respective merits of different methods of treatment. Still, the marked difference in results is so commendatory of the antiseptic method that a reasonable degree of error in compilation can be admitted without materially lessening the contrast between the two methods.

A very recent report of the results of over twelve hundred surgical wounds and accidents, treated antiseptically with corrosive sublimate, shows a mortality of only five per cent., and only one death could be attributed to the toxic effect of the antiseptic. More than three fourths of these wounds, over nine hundred in number, united by first intention, while more than one half of the balance healed by second intention. The serious nature of many of these wounds is apparent when it is understood that of the whole number 91 were major amputations, 117 were resections of portions of the long

bones, 91 were compound fractures, 69 were joint operations, 81 were operations for hernia, 3 for removal of the kidney, 25 for ovariectomy, and 8 for resections of the intestines.

Formerly the mortality of cases of compound fracture of the long bones averaged one in every four. The complicated nature of this double wound in every way favored the absorption of septic material. The long-continued suppuration reduced the vigor and vitality of the constitution, while at the same time it delayed indefinitely osseous union.

A remarkable change in the results of these injuries has been occasioned by antiseptic treatment. This consists in practically closing the external wound at once by the dressing. The danger of septicæmia is thus greatly diminished, suppuration is prevented, and the bone unites with the same facility and rapidity as in cases of simple fracture, while the mortality is reduced to about the same ratio as that following fractures uncomplicated with an external wound.

Some of the most brilliant achievements of modern surgery are the results of operations involving the exposure and exploration of the abdominal cavity. The protection afforded by the exclusion of germs has rendered these operations successful, although formerly they were so uniformly fatal that their performance was considered unjustified, except as a last resort.

Fifty per cent. of recoveries used to be thought a fair and reasonable expectation in operations of ovariectomy, the mortality being caused in a large majority of the cases by septicæmia or septic peritonitis. At the present time the death-rate of unsuccessful cases is reduced to about ten per cent.

When every condition is favorable ovariectomy is almost invariably successful, provided modern rules and precautions are observed and a fair degree of skill is exercised. The astonishing success attained in this particular operation is unquestionably the result of a comprehension of the principles and faithful execution of the details involved in the antiseptic method. Other operations, requiring exposure of the abdominal cavity and its contents to the influence of the external air and the irritation of manipulation, have also proved surprisingly successful. In a corresponding degree have the results of most other surgical operations been favorably influenced by this method. Excision of joints, excision of portions of shafts of bone, opening into and exploring joint-cavities, amputation to check senile gangrene, besides many other operations which, in former times, were considered extremely doubtful as to results, are, at the present day, performed with an assurance of success not dreamed of thirty years ago. In fact, there are few, if any, external wounds known to surgery that have not, at least in some degree, contributed to the vast and increasing fund of accumulated testimony which establishes the great importance of the principles embodied in antiseptic surgery. Allusion has been made to the importance of recognizing the fact that there is a limit to the beneficial application of antiseptic agents. Since this limit has become more distinctly defined and its value more fully appreciated, there has been increased success in wound treatment. It is also important to remember that the antiseptic agent employed is not necessarily the

*sin qua non* of the method, but that success depends largely upon the faithful, intelligent, and persistent execution of the details required to prevent inflammation. It is unnecessary to say more. Even now I have trespassed too far upon your good nature in stating facts that are an open book to the profession. The subject is worthy of a more facile pen than I can wield, and should be presented by one who has more perfect knowledge than I possess and a wider experience than I have enjoyed. The knowledge that I am addressing to-day some who are endowed with these accomplishments does not deter me from exerting my influence, however slight it may be, to induce every member of this Society to avail himself of the advantages connected with the practice of antiseptic surgery. The fact that there are scores of physicians in this Commonwealth, members of this Society, who have never fully employed the antiseptic method in wound treatment places me under an obligation as a medical brother to convince them, if possible, of its superior merits as compared with other practice. To assert that antiseptics, especially carbolic acid, are not generally employed by my fellow country practitioners would be most assuredly false. But they are not applied in a manner to secure the advantages entitled to the antiseptic method. In the form of lotions and washes they do exert, to a certain extent, a beneficial effect, but the protective dressing, upon which depends the question of putrefaction in most wounds, is practically omitted except by a minority of physicians. The application of lotions to fresh wounds is of very slight importance in comparison with the value of protective dressings to prevent the access of germs during the process of healing. However, to omit either the lotion or the dressing, except in special instances, is a violation of antiseptic rules. The best results have been obtained by surgeons who have most carefully observed all the requirements and details of the treatment. Furthermore, in addition to strictly professional reasons for using this method, there is to be considered the claim of the patient. The members of the medical profession are not the real beneficiaries of the antiseptic treatment. Our patients have a right to enjoy the advantages and blessings conferred by antiseptic surgery and it is our moral duty to afford them its benefits. The only apology entitled to acceptance that a member of this Society can offer a patient for neglecting to employ this treatment is a lack of familiarity with its principles and details. This, however, is so easily acquired at the present time that even such excuse should barely suffice to satisfy the expectation of the patient. If the presentation of this subject to-day results in stimulating my associates who are united with me in the rural practice of our noble profession to adopt more completely the principles and practice of antiseptic surgery, the present hour will not have been unprofitably employed.

— Two hundred and forty of the Boston police received diplomas of the Massachusetts Emergency and Hygiene Association this spring, having attended and passed an examination upon the lectures provided by the Association the last winter.

CASES OF CEREBRAL SYMPTOMS IN EARLY (SECONDARY) SYPHILIS.<sup>1</sup>

BY F. B. GREENOUGH, M.D.,

Physician to the Boston Dispensary, Department of Skin and Venereal Diseases.

THESE five cases, which, excepting the first, which occurred in 1878, have been seen in my private practice during the past two years, showed symptoms of cerebral trouble, coming on during the early period of syphilitic infection, respectively six, four and a quarter, eight, four and a half, and five months from the appearance of the primary lesion, or on an average of five and a half months. They all were preceded by severe cephalalgia, all showed partial paralysis of certain muscles, and, with the exception of the fatal case, all yielded quickly to treatment. With one exception, Case IV., they were cases in which the manifestations on the skin and mucous membranes were decidedly mild and of short duration. It is perhaps fair to assume that if Case IV. had continued under regular treatment, instead of getting into the hands of a quack, his secondary symptoms might not have been as severe as they were when I first saw him. They certainly disappeared very quickly after he came under my care. I refer to the mildness of the secondary symptoms in these cases, as it confirms the statistics which other observers have collected, which go to show that in the majority of cases where cerebral symptoms show themselves early the previous manifestations have not been of a severe type. I think, however, that it would be very far from the truth to infer, on that account, that the fact of a case of syphilis showing a mild and benign type, as far as the manifestations on the skin and mucous membranes go, is an indication that cerebral trouble is to be anticipated; in other words, that a mild course of development of the constitutional symptoms is a bad feature in a given case. This is far from being so, as a large number of the cases, which run a mild course and in which the symptoms disappear quickly under treatment, not only do not have any cerebral trouble, but are exempt from relapses of any kind. In all five of these cases headache was a prominent premonitory symptom, and, moreover, a headache having certain well-marked and definite characteristics, such as its decided tendency to exacerbations toward evening, its severity, and its very quick yielding to the administration of the iodide of potassium. While cases of early cerebral specific trouble are rare, cases that complain of cephalalgia, exactly identical to that described, are quite frequent. I have seen many that I am convinced would have resulted in cerebral trouble had they not been recognized and properly treated. The proportion of these cases in dispensary practice is much greater than those observed at my office, and as the former class of patients are much less under control, to say nothing of their being so situated that they are unable to get proper care, nourishment, etc., and do not follow out the instructions given, it is not to be wondered at that such is the case. The fact that in patients who are careless or

unable to follow up the treatment prescribed the symptom of early syphilitic cephalalgia, with the possibility of the occurrence of cerebral symptoms, is comparatively frequent, is of course a strong proof of the need of regular treatment as a safeguard, to say nothing of giving the patient relief from what is at times an excruciatingly painful symptom. The appearance of a patient who has been suffering for some days from this specific headache is very characteristic. Even if seen early in the day, before the attack comes on, they show a worn and wearied expression. I have not been able to corroborate the statement made by some of the writers on this subject that these headaches are usually confined to one half of the head. On the contrary, my experience has been that they are either frontal or occipital, in the early stages chiefly the former. Some patients describe the pain as feeling as though there was a great pressure inside the skull, or, as one expressed himself, as though his "whole brain had swollen, and was too big for its box." Others, again, refer the pain more to the exterior, and even complain of tenderness to the touch of certain points of the scalp.

Prof. LeGrand N. Denslow, in the *Northeastern Lancet*, May 1, 1885 (vol. iv, No. 14), reports four interesting cases of "Persistent headache in early syphilis," in all of which the phenomena were observed within six months from the appearance of the chancre. In one of the cases, where treatment was neglected, complete hemiplegia, with aphasia, came on, and, although the patient recovered, at the end of a year there still remained marked hesitancy in speech. He got excellent results in these cases, as early as two or three days after commencing treatment, by administering minute (one twentieth of a grain) doses of calomel hourly. I will refer later to this question of treatment.

With regard to the influences which may act as predisposing causes in producing cerebral symptoms in syphilis, the writers on the subject, especially Fournier and Heubner, have made thorough investigations. Beyond the influence of the weak spot, the *pars minoris resistentie*, they find that excesses in venery, abuse of alcohol and tobacco, great fatigue either physical or mental, mental griefs or shocks, etc., may act as such. In the cases I have reported nothing of especial interest in this line of investigation is to be noted.

The diagnosis of these early cases of cerebral syphilis is very much simplified by the fact that they occur either while the symptoms of constitutional infection on the cutis and mucous membranes are still apparent, or so shortly afterward that the fact of the patient's having recently had syphilis could not very well be ignored. Their diagnosis, however, by no means depends on this point of time alone. The fact that the attack had been preceded by the characteristic headaches which I have described would be of importance. The muscular paralysis in these cases is always, at first at least, an incomplete one; loss of power or of control of one arm or leg, or both, is first noticed, and this gradually increases. A certain amount of aphasia, or rather a hesitancy in speech, seems to be a pretty constant symptom. The comparative youth of the patient in many cases is of diagnostic value. Lastly,

<sup>1</sup> Concluded from p. 571.

the fact of the symptoms improving under specific treatment would, of course, decide the question. The lesion which is most likely to be confounded with these early cases of cerebral syphilis is an embolus of a cerebral artery. In such a case, however, the symptoms of paralysis would come on more suddenly, be more complete, and there probably would be some indication of the cause of the embolus.

While the *pathology* of cases of late cerebral syphilis has been very thoroughly studied by the French and German pathologists, these early cases have not been, or at least I have not been able to find much on the subject. The important point, practically, is to know whether these cases are the result of a precocious development of the neoplasms which, as a rule, are only found in the later stages of the disease, or whether the symptoms are produced by a simply temporary, inflammatory process affecting the meninges of the brain itself, which corresponds to the macula on the cutis, and the superficial mucous patches of the mucous membranes, and which leaves no structural alteration behind it. Heubner, with the characteristic caution of the German scientific observer, who refuses to go one step beyond the path which his scalpel cuts out for him and his microscope illuminates, says, with regard to this point, that "while not denying the possibility of intercranial simple inflammation of syphilitic origin existing, neither originated nor accompanied by a new formation, the cases so far reported are not sufficient to justify it, and for the present it must be regarded as an open question." From a clinical point of view it seems unlikely that these cases of early cerebral syphilis, which show themselves simultaneously with symptoms on the skin and mucous membranes due to simple inflammatory action, and which yield almost at once to treatment, should be caused by a different pathological process in the nervous system from that which is manifest elsewhere, and the question presents itself, whether in the same way, as we see at an early stage of the disease, the periosteum of certain bones, such as the sternum, the clavicles, and the tibia, become tender, painful, and swollen, all of which symptoms disappear rapidly under treatment, the same thing may not take place in the dura, and by pressure give rise to the cerebral symptoms noticed.

Fortunately, when we come to the question of *treatment* of these cases we leave all regions of uncertainty and doubt, for if there is one proved fact in medical science it is that in the iodide of potassium we have a specific in the true sense of the term. Of course, there are exceptions to every rule, and more especially so in medicine, but in spite of the many examples I have seen of its efficacy I am constantly astonished at the almost immediate result of this drug in cases of syphilis where its use is indicated. Time after time patients will come, complaining of the most excruciating headache, which has been torturing them for weeks, and on the second day they will report themselves as absolutely freed from their trouble. The importance of giving the iodide in all cases of syphilitic headache as not only a means of saving the patient from great suffering, but as a prophylactic against more serious cerebral

symptoms in the future, is, I think, the most important practical deduction to be drawn from the cases I have reported. While I would insist upon the use of the iodide in these cases, I would by no means be understood to deny the importance of a mercurial course. On the contrary, if we want to give the patient the full benefit of treatment, and, more especially, guarantee him as far as possible from relapses, the advantage of a mercurial which should be continued even after all indications for the iodide have ceased is absolutely necessary. The old dictum—secondary, mercury; tertiary, iodide—no longer holds. The fact is that in mercury properly administered we have a true specific for the treatment, and I think I can venture to say for the cure, of syphilis in whatever stage or period it may be, where its use is not contraindicated, while in the iodide of potassium we have an equally powerful specific to use against *certain symptoms*, at the head of which stand those affecting the brain. I have not found that it has been necessary in these early cases to push the iodide to the very large doses that we see reported; ten, fifteen, or twenty grains three times a day will generally show decided results. On the other hand, I have seen cases where the patients had been doubling up on their doses of iodide and getting daily worse, improve most decidedly on having the iodide cut down to a very moderate amount and a mercurial added to it. Where the mercurial is administered internally it is well to combine the iodide with some simple bitter, and have it taken just before meals and the mercurial after. In cases, however, of present or threatened cerebral trouble a more rapid and thorough action of the mercurial is indicated, and inunctions are very efficacious. The method mentioned by Dr. Denslow of giving small and frequent doses of calomel will act even more rapidly than inunctions, but the patients must be watched very carefully, as the chances of salivation must be taken into consideration. It may be asked why, if the treatment by inunction is the most successful one, not always use it? To this I would reply that, in point of fact, most patients do very well under internal treatment. I am referring now to the general treatment of syphilis, and as long as they do so it is just as well to reserve our most powerful weapon for any emergency that may arise. Moreover, the process of inunction is so dirty and troublesome that few patients, in my experience at least, can be kept on it for any length of time.

With regard to the prognosis of these cases of early cerebral syphilis it is, of course, too soon to draw any deductions from those I have reported. One of them, Case II., seems absolutely well, but it is only two years since his attack, and, of course, too soon to feel sure as to the future. That cases in which such serious symptoms show themselves so exceptionally early should be warned as to the need of their giving themselves the full benefit of careful life and regular habits there can be no doubt. Fortunately as we are in the possession of methods of treatment, which in many cases will overcome the threatening symptoms, we must feel that there is always a possibility of permanent injury having been done to one of the most important of the vital organs.

RECENT PROGRESS IN PATHOLOGY AND  
PATHOLOGICAL ANATOMY.

BY WILLIAM F. WHITNEY, M.D.

## THE PATHOLOGY OF LIPOMATOSIS UNIVERSALIS.

KISSEL<sup>1</sup> has given his attention to obesity and some of the results which can be directly attributed to it are incorporated in a paper with the above title. He premises by saying that the line between a physiological production and a pathological condition is not always easy to draw, and that the proposition which states that fat should form one twentieth of the weight of a man and one sixteenth of the weight of a woman is of no practical clinical worth. It is shown that the pathological condition begins first in those places where this condition is normally very abundant: in the subcutaneous tissue, mesentery, larger omentum, perinephritic tissue, mediastinum, pericardium, etc., and it is not until the disease has reached a high degree that much is found in those places where very little is normally present: between the muscular fibres, under the endocardium, and in the glandular organs, liver, and kidneys.

Two forms are recognized: the hereditary and acquired. The predisposition cannot be denied, and almost every one can recall families, the members of which become very fat, uninfluenced by their manner of living or abode. Cohnheim assumes in such cases that the oxidizing process does not go forward with normal energy, but he does not entirely ignore the idea that the hæmoglobin (the oxygen carrier) may be too small in amount in the red corpsesules of the blood.

As an example of this form the author cites one family in his own practice in which was a girl sixteen years old who weighed 142 kilos (300 lbs.), a boy of fourteen who weighed 135 kilos (290 lbs.), and a girl of ten years weighing 81 kilos (178 lbs.). The prognosis in such cases is very unfavorable, as treatment seems to be without result, and one of the complications to be mentioned later soon puts an end to existence.

The acquired form is in the great majority of cases to be directly referred to improper mode of nutrition. A rich albuminous diet in combination with considerable quantities of starch and sugar, muscular inactivity, and an insufficient supply of oxygen are able to increase the fat to a pathological degree. An example of this was found in a well-to-do merchant, thirty-six years of age, who weighed 192 kilos (420 lbs.), whose circumference at the umbilicus was 186 cms; the upper arm measured 56 cms., the thigh 91 cms., the knee 50 cms., and the calf of the leg 56 cms. The abdomen was so heavy that he was obliged to have a second chair on which to support it.

In such people the danger of sudden death is very great.

In the first place, changes which are induced in the heart may cause this. This organ is burdened in two ways. In the first there is a direct increase in the call made on its activity by the increased bodily weight, and on the other its power of work is directly decreased in a manner parallel with

the increase of fat, since in the tissue thus newly formed there are new vascular districts, which increase the quantity of blood and the resistance. This augmented work is rendered still more difficult from the fact that a growth of fat has also taken place upon the surface of the heart, and has penetrated between its fibres, which at last become degenerated. The strain on the heart is rendered still greater, in many instances, by an arteriosclerosis. This seems to be a common accompaniment of excessive corpulence, and by it the elasticity and contractility of the vessels are impaired, and thus a hindrance is given to the onward motion of the blood.

For a time, as is well known, these demands may be met by a compensatory hypertrophy and dilatation of the left ventricle, and then by the same condition of the right. It is then that palpitation and dyspnoea become urgent after any bodily exertion, often accompanied by vertigo. Objectively the area of the heart's dullness is increased, its impulse is directed outward and only to be weakly felt. The tone is muffled and at times accompanied by a short murmur or double tone. The pulse is rapid or slowed or dicrotic. Later the action becomes very arrhythmic and is very feeble. Neuralgic pains of various kinds streaming out from the region of the heart into the left shoulder are annoying symptoms.

In the majority of cases the fatal end is brought about by the gradual failure of the heart, accompanied by universal dropsy, general loss of strength, or by paralysis from cerebral hæmorrhage.

Occasionally death is sudden from paralysis of the heart or from œdema of the lungs. Next in importance to changes in the heart are those in the lungs, which may lead to fatal complications. On the one hand the accumulation of fat on the thoracic walls renders the respiratory movements more difficult, while on the other that in the abdominal cavity pushes up the diaphragm and so restricts the respiratory space. This can be compensated for by a quickening of the respiration, but gradually there is set up a catarrh of the finest bronchi, due to the compression of the lung combined with the passive hyperæmia, resulting from the weakened heart. This can easily take on acute exacerbations, from accidental irritation of the air-passages, causing alarming dyspnoea. Further, a tendency to pneumonia seems to be developed, which is apt to be very fatal.

The kidneys frequently present symptoms of the disturbance in the balance between the arterial and venous systems. The urine is diminished in amount, dark-brown in color, of a high specific gravity, and with a marked separation of urates or crystallized uric acid. Albumen is constant but varies in quantity, with a few small casts, and here and there epithelium from the tubules, with blood corpuscles. As a consequence of this comes œdema and anasarca, with effusion into the serous cavities. The renal complications are most to be dreaded in cases of chronic alcoholism.

The following table of the results of eighteen autopsies, where obesity seems to have been the primary lesion, show the organs in the order affected:—

<sup>1</sup> Wien, Medic. Presse, March 1, 1895.

## CHANGES IN THE HEART.

Simple hypertrophy of the whole heart . . . . .	5
Eccentric hypertrophy of the whole heart . . . . .	3
Dilatation of the right side of the heart . . . . .	3
Signs of fatty degeneration of the heart . . . . .	7
Signs of arterio-sclerosis . . . . .	13

## IN THE BRAIN.

Hæmorrhage . . . . .	6
----------------------	---

## IN THE LIVER.

Fatty infiltrated liver . . . . .	9
Cirrhosis . . . . .	2
Gallstones . . . . .	2

## IN THE KIDNEYS.

Passive congestion . . . . .	5
Parenchymatous degeneration . . . . .	8
Advanced granular atrophy . . . . .	2

## IN THE LUNGS.

Emphysema . . . . .	5
Pneumonia . . . . .	5

From this it seems that in two thirds of the cases hypertrophy and dilatation of the heart were present, and in more than one third fatty degeneration was associated with the infiltration. In more than three fourths of the number signs of arterio-sclerosis were present and this often, too, in young individuals. In about five sixths the kidneys were affected, varying in degree from simple passive congestion to extreme interstitial nephritis. One third died from cerebral hæmorrhage, while in one half a fatty liver was present.

THE THYROID GLAND: ITS RELATION TO THE PATHOLOGY OF MYXŒDEMA AND CRETINISM, TO THE SURGICAL TREATMENT OF GOITRE, AND TO THE GENERAL NUTRITION OF THE BODY.

Under the above title Horsley<sup>2</sup> has recently delivered two lectures in which light is thrown upon the functions of this ductless gland and its close relation with certain diseases.

*Anatomical Peculiarities.* The arterial blood-supply is very abundant, the area of the arteries being estimated as equal to that of the brain. Along the course of these are large lymphatic spaces, as well as around the borders of the alveoli. The nerves found in the stroma appear to have chiefly a vasomotor function. The question whether the acini communicate and thus form a ductless racemose gland is still undecided. Everything seems to point to the view advanced by Heber that the mucinoid contents of the spaces are excreted from the blood by the lining epithelium and that reabsorption is affected by the large lymphatics.

*Function.* Two distinct views have been advanced in regard to this: (1) That the gland acts as a regulator of the cerebral circulation; (2) that it secretes something necessary to the perfect nutrition of the brain.

The first rests chiefly for its support on the anatomical proof of the close relationship of its arteries with the carotid, and on the fact that after long efforts the pulsation of the carotidean branches is stopped by the pressure of the gland on the main artery, produced by the contraction of the cervical muscles upon it. By others it is regarded simply as a mechanical bolster.

The second view rests on the results of excision.

It has been found that a person in whom the gland was entirely removed became idiotic (*a cretin*), and that the same operation on dogs caused great nervous disturbance; they also became idiotic, and finally died comatose. It is especially in the experimental direction that the author has turned his attention, and his results tend not only to confirm the above facts but go to show that the disease, first accurately described by Dr. Ord and called by him myxœdema, can also be induced in monkeys. He considers, however, that this is only a phase in the disturbance of nutrition and, like cretinism, is the effect of some undetermined law.

The wound after the operation (for the details of which the original is to be consulted) was entirely healed at the end of three days, and the post-mortem examination in all cases showed that the gland had been entirely removed and that there had never been any injury to the sympathetic or its branches. So that the theory that looks to changes in this last falls to the ground.

The phenomena which follow the extirpation of the gland may be summarized as follows: Within five days of the time of the operation the appetite fails for a day or two, and upon close inspection a slight but constant fibrillar tremor of the muscles of the face, hands, and feet is evident. This disappears upon voluntary movements. The animals grow pale and thin in spite of the marked appetite which has returned, the tremors increase and affect all the muscles of the body without exception, they become languid and paretic in their movements, and finally imbecile. Puffiness of the eyelids and swelling of the abdomen follow with the increasing hebetude. During the last stages the temperature gradually falls until it becomes subnormal, and then the tremors gradually disappear as they came. Meanwhile the pallor of the skin becomes extreme, leucocytosis is well marked, upon which oligæmia follows and the animal dies perfectly comatose, at a variable time, but usually within five or seven weeks after the operation.

The tremors are from a central origin or else idiomatic. They are accompanied by a marked paresis and rigidity of the muscles, which varies directly as their force. At times a slight increase in power is observed, but as a rule there is a steadily increasing weakness.

The cerebral symptoms are gradually progressing dulness terminating in partial or complete imbecility. In the advanced stages they take no notice of anything going on about them and only rouse up to eat. The same listless air as in cretinism is observed. There is little change in the emotions beyond that they are easily enraged in the same way that idiots are, and there is almost or complete inhibition of voluntary power.

A point of special interest is the enormous amount of hypertrophy which the salivary glands undergo. This is unaccompanied by pain and probably due to an increase of mucin (on analysis sixty times the normal amount was found to be present). Physiologically this is of importance, as the parotid, which is normally a serous gland, has become a muciparous one. The spleen is enlarged, and the abdomen swells as in true myxœdema. This latter condition is due to a hypertrophy of the great omentum and

distention of the intestines. The peritoneal fluid is slightly increased and contains mucin.

The skin is also swollen, the eyelids become so puffy and elastic as to diminish the palpebral fissure one half, while the general look of the face becomes pathognomonic of the disease above mentioned. Dryness of the skin has not been noted, but there was one example of atrophy of the hair.

*Pathological appearances.* Upon turning back the skin of an animal that had lived for more than a month the subcutaneous tissue was found swollen, jelly-like, bright, shining, and excessively sticky. This is especially marked over the triangles of the neck and the hypochondrium. The same condition is also found in the loose tissue of the mediastinum and in the omentum, along the line of the coronary arteries, and the auriculo-ventricular groove. The fat in this increased tissue is as a rule atrophied.

The changes may be characterized as a hypertrophy of the fibrous tissue elements coupled with mucoid transformation of the ground substance, and accompanied by disappearance of adipose tissue.

The increase in size in the parotid and submaxillary glands was due to a semitranslucent pale enlargement of all their lobules. From the cut surface a glairy, sticky fluid exuded, quite the reverse of that found in health. Microscopically the cells of the parotid were seen to be distended by mucin or a substance closely allied to this, and in extreme cases were destroyed, and recalled the goblet cells of the intestine. The mucosa of the intestinal tract appeared swollen and had a semitranslucent appearance, while in four cases there was an increase of mucus in the excreta, in one case forming firm, tenacious strings.

As to the swelling of the tongue which has been noted in man it could not be clearly proved here, as that organ in the monkey is normally very large.

The increase in the size of the spleen is due to simple hypertrophy.

In the central nervous system the brain and cord were very pale, the sulci deeply marked, and the meshes of the pia mater distended with fluid. In short, there is some wasting of the convolution.

The peripheral nervous system showed no change to the naked eye, neither did the sympathetic nor musculo-spinal nerves.

The author thinks that no one would be prepared to formulate a theory of the full pathology of the conditions that have been described in the present state of the subject. Certain facts are, however, so striking that they will perhaps aid in further investigations and he has enumerated them in a tabular form, first taking the anatomical and then the physiological.

(1) The thyroid gland appears to consist of two distinct portions: (a) glandular, consisting of highly vascular acini which excrete into the interior a mucoid substance, and this or something very similar is found again in the lymphvessels of the gland; (b) highly vascular lymphoid nodules which have a hæmatogenous function.

(2) Excision of the gland is followed by an increase in amount of mucin in the tissues which normally possess it, by an increase in the activity of the glands which secrete it, and by the assumption

of the muciparous functions by glands which normally produce very little or no mucin.

(3) Excision of the gland is followed by profound changes in the blood, namely, a diminution in the number of the corpuscles, preceded in the case of the white ones by a temporary increase in their number; an alteration in the albumens and in the presence of mucin.

(4) Excision of the gland is followed by nervous symptoms indicating changes in the lowest nervous centres as well as in the highest psycho-cortical ones.

The practical point to be drawn from all this in surgical operations is the necessity of refraining from total extirpation of the thyroid except in the gravest cases (malignant disease), and that where simple goitre is to be combated excision of the isthmus is the procedure to be recommended both on practical and theoretical grounds.

#### ON THE PATHOLOGICAL CHANGES IN BILIOUS TYPHUS FEVER.

In the early times when recurrent fever was first set off from the other forms of typhus, this peculiar form was not recognized, and it was Griesinger, in 1850, who first gave it the proper position. He characterizes it as a severe form of remittent which is localized especially in the spleen and bile ducts. From the fourth to sixth day onward there is marked icterus and stronger subjective symptoms, while the regularity of the paroxysms often fails.

From that time there have been two opinions held: one that the disease is simply a form of relapsing fever; the other that it is an independent affection.

Lübmoff<sup>3</sup> has had an opportunity of studying this in an epidemic in which twenty-four cases came to autopsy.

The spleen was the organ which most attracted attention. It was enlarged, often to an extreme degree, the largest weighing 1,845 grammes.

In some cases the surface of the cut section was studded with white or yellow specks, the size of poppy or hemp seed, surrounded by the cherry-red, comparatively firm parenchyma of the organ. These were often so numerous that they became confluent and foci as large as a pepper-corn resulted. The microscopic examination showed that they were enlarged follicles. The parenchyma contained, besides its normal constituents, cells holding red blood corpuscles in their interior. The endothelium of the small veins was swollen and loosened from the walls.

In other cases there were found grayish-red or grayish-yellow infarctions reaching to the surface or the anterior edge and varying in size from a pea to one fourth of the entire volume of the organ. These nodules in the majority of cases were separated from the surrounding tissue by narrow spaces filled with a thick, yellowish-green, odorless pus. In the neighboring parenchyma there were seen, after proper staining, dark-blue tube-like masses, which were found to be bloodvessels thrombosed by micrococci or filled with red blood corpuscles and micrococci. In the vessels free from these, the

endothelium had been cast off, forming accumulations of epithelioid-looking cells completely blocking up the lumen.

In one case finally there were multiple abscesses, one of which had worked its way through the diaphragm and was only prevented by adhesions from breaking into the pleural cavity. In this case there was a softened thrombus in the splenic vein.

In the liver the cells showed evidences of marked granular or fatty degeneration. Micrococci were found in the intralobular veins and in two cases there were small abscesses.

In the kidneys there were found parenchymatous swelling and acute interstitial inflammation, the latter distinguished by the presence of minute abscesses in the pyramids and cortex. In these abscesses there were to be distinguished three zones: a deep-colored central one composed of microorganisms, a middle one of coagulative necrosis, while the outer was formed of canals which had undergone an intense parenchymatous inflammation.

The heart presented appearances indicative of various degrees of fatty degeneration; while the elements of the nervous system showed signs of a parenchymatous one.

In the stomach and intestines there were punctate hemorrhages of the mucosa as well as evidences of an acute catarrh. The vessels of the mucous membrane, submucosa, and muscularis were often plugged with micrococci.

In the bone marrow there were found small hemorrhagic centres, in the peripheral layers of which, as well as in the medullary vessels, colonies of micrococci were present.

The lungs were oedematous, or else had bronchopneumonia or pneumonic infiltration.

The author has found the spirilla of recurrent fever in the blood of the patients examined during life, and upon this he explains the occurrence of the infective lymphomata which are found in the spleen. The other changes are to be explained on the ground of a co-existent pyæmic or septic condition, and he therefore regards bilious-typhus simply as a complicated variety of remittent fever and not as an independent disease.

## Reports of Societies.

### THE ONE HUNDRED AND FOURTH ANNUAL MEETING OF THE MASSACHUSETTS MEDICAL SOCIETY.

JUNE 9TH AND 10TH.

For this occasion the Fellows were favored with the perfection of June weather, and an interesting, profitable, and agreeable series of gatherings occurred. The streets were clean and hard from recent rains, the air bright and clear, and what is not often the case at this season, the temperature at the same time cool and bracing. The usual provisions were made for the day previous to the anniversary proper. The place of meeting was, as for the past two years, at Huntington Hall in the building of the Massachusetts Institute of Technology in Boylston Street, Boston.

### AT THE HOSPITALS.

On Tuesday morning, June 9th, quite a large number of the members of the Society accepted the invitation to visit the various hospitals. In the wards of the City Hospital a number of antiseptic dressings were exhibited by Dr. Bolles, and attention was called to the excellent results which had followed a careful carrying-out of antiseptic principles. Fracture dressings as usual attracted considerable attention and in particular the demonstration by Dr. Brewer, house officer, of the method of application of the plaster posterior splint. Among the operations witnessed were an amputation of a portion of the foot by Dr. C. D. Homans, sequestromy by Dr. Bolles, a plastic operation of the nose by Dr. Gay, and two operations each for cataract and strabismus performed by Dr. Williams without ether and with the use of cocaine. Drs. Gay and Bolles each exhibited the results of plastic operations done some years ago, the former upon the nose, and the latter upon a crushed hand in which the power of apposition of thumb and little finger was retained, the intermediate portions being removed. Among the interesting medical cases shown was one of subclavian aneurism by Dr. Lyman.

At the Children's Hospital the visitors witnessed an operation for cleft palate and also an osteotomy. A successful case of trephining for epileptic convulsions was exhibited by Dr. Cabot, in which the convulsions from having been six to twenty daily ceased entirely after the operation. The practical application of various orthopaedic apparatus was shown, and various little details promotive of the comfort of children during confinement to bed were wisely considered of sufficient importance to be noticed. At the Massachusetts General Hospital an amputation of the thigh was performed by Dr. J. C. Warren.

### FIRST SESSION.

The first session opened on Tuesday at noon. Dr. CHAS. D. HOMANS, President of the Society, in the chair. Rather a small number of members were present, many remaining at the various hospitals to witness the conclusion of interesting operations.

The first paper was on "The Pathogenesis of Certain Affections of the Skin," by George N. Tilden, M.D., of Boston.

It dealt principally with the power of various drugs in common use to cause certain symptoms in the skin, and discussed the method in which these effects were probably produced. Much care was shown in its preparation.

The second paper on "Consauguineous Marriages: Their Effect upon Offspring," by Charles F. Withington, M.D., of Roxbury, contained the results of a large series of consanguineous marriages, collected by the writer. The conclusion drawn from an analysis of the figures was that where evil results followed such unions, they were due to a combination of morbid qualities in the parents and not to the simple fact of consanguinity.

In the brief discussion which occurred Prof. H. P. Bowditch alluded to a case spoken of by Professor Baelz, of the Royal University of Tokio, Japan,

while on a recent visit to this country, where on a small island of Japan there was an isolated community which had intermarried very closely, so that all the individuals were related, forming as it were one great family. Yet they were an exceptionally well-developed race and free of any marks of mental or physical deterioration. Dr. Brown, of Barre, in charge of an institution for defective youth, said that in his experience Dr. Howe's figures on the proportion of consanguineously descended among the idiotic was wide of the mark. In Dr. Brown's institution the proportion was about five per cent.

The concluding paper of this session, and one of much interest, was by J. R. Chadwick, M.D., on "Labor Complicated with Fibroids."

Adjournment was made shortly before two, and the Society reassembled in large numbers at four o'clock, when the following papers were presented: "The Climatic Treatment of Phthisis," by Harold Williams, M.D., of Boston. "How a Lesion of the Brain Results in that Disturbance of Consciousness known as Aphasia," by Morton H. Prince, M.D., of Boston. "The Relation of Insanity to Certain Nervous Affections," by Henry R. Stedman, M.D., of Roslindale.

These papers were all thoughtfully written and were received with much interest by the members present.

#### EXHIBITION OF APPARATUS.

During Tuesday and Wednesday an interesting exhibition was given in one of the lower rooms of the Institute of Technology. It comprised electrical apparatus in considerable variety, including Toepfer-Holtz machines, and galvanic and Faradic batteries in a large variety of styles and manufactures for office use and in portable form. Especial interest was shown in the Curt battery and the adaptations thereby of electric illumination to the cavities of the body. Dr. Robert Amory exhibited a variety of delicate electrical apparatus adapted to medical and surgical uses, galvanometers, etc.

As usual, arrangements had been made for the exhibition of original mechanical and surgical appliances by members of the Society and a number of interesting devices were shown, of which we can only speak briefly. Perhaps foremost in historic interest was a case of instruments arranged by Dr. H. I. Bowditch to illustrate the "evolution of the stethoscope," beginning with the earliest attempts of Laennec in 1816, and passing through various intermediate types down to the perfected double instrument of Cammann. The long and the short, the thick and the thin, the plain and the "fancy" types were all there, including the notable instrument of Dr. Jacob Bigelow, with plessimetric attachment alluded to in Holmes's "Stethoscope Song."

The exhibition of the Massachusetts General Hospital showed the old-time elegance of bandaging which is so intimately associated with that institution, and which was especially striking in the somewhat difficult situations of shoulder and axilla. The sterilized cotton dressing employed by Dr. Warren was shown, as well as the apparatus used in its preparation. The Children's Hospital afforded a number of orthopaedic appliances, among them a club-foot crusher and a head-rest for use in cervical

caries. Rubber abdominal, vaginal, and cephalic coils for reducing temperature were also shown.

The chief centre of attraction among the apparatus was, perhaps, the pneumatic cabinet, designed by Dr. Herbert H. Williams, of Brooklyn, New York, and exhibited by Dr. Vincent Y. Bowditch. It consists of a cabinet large enough to contain a patient in a sitting posture, and with an air-pump attached whereby any desired degree of rarefaction can be produced in the contained air. An opportunity was afforded the Fellows of witnessing its practical operation. The individual operated upon, taking his place in the cabinet, places his mouth in connection with a tube communicating with the external air, and, as a slight exhaustion is produced in the chamber, he breathes an atmosphere denser than that in which he sits. By an atomizer placed in connection with this tube any desired medicated fluid may be introduced, as is claimed, deeper into the alveoli of the lung than could be otherwise done. The initial rarefaction of the air made was only to an extent corresponding to one tenth of an inch of barometric pressure, but the exhaustion may be carried to the extent of two or three inches of the mercurial column if desired and as the exigencies of the case may seem to require.

#### CONFERENCE OF CENSORS.

At half-past two o'clock the annual conference of censors from the different District Societies throughout the State was held at No. 19 Boylston Place. Dr. John Crowell, of Haverhill, north district, presided, and the principal topic of discussion was: "The Examination of Physicians for Admission to the Massachusetts Medical Society, and the Desirability of a Uniform Examination Throughout the State." Remarks were made by a number of gentlemen present. After some discussion Dr. F. C. Shattuck offered the following resolution, which was adopted:

*Resolved*, That this meeting has heard with pleasure of the conformity to the By-laws in the matter of examining candidates for admission to the Society, and hopes for further progress in that direction.

The following motion of the Secretary was also carried:—

*Voted*, That the delegates of the District Board of Censors be required to report the doings of this conference to their several boards, and that each be urged to send a full delegation to take part in the future deliberations of the conference.

The meeting then adjourned.

#### COUNCILORS' MEETING.

In the evening at seven o'clock the annual meeting of the Councilors was held.

After this meeting a numerously attended and very pleasant reception was given by Dr. C. D. Homans, the President, at his residence in Boylston Street, to the Councilors and guests of the Society.

#### WEDNESDAY MORNING.

At nine o'clock A.M., the meeting was called to order by the President, Charles D. Homans, M.D. The records of the previous meeting were read by the Secretary, Dr. F. W. Goss, and approved. Dr. F. W. Draper, Treasurer of the Society presented his report, by which it appeared that with a balance

of \$1,562.86, the receipts for the past year have been \$10,022.75; the expenses were \$8,312.20, leaving a balance of \$1,710.55. The invested funds amount to \$32,420.17.

It was announced that for non-compliance with certain By-laws twenty-two members have been dropped from the rolls. The present membership numbers 1,578. During the year ten women have been admitted to the Society.

The committee to which the resolution offered at the last annual meeting by Dr. Asa Millett, relative to the examination of persons seeking certificates of ability to practise, irrespective of place of study, made a report that the same ought not to pass, as the By-laws of the Society now cover the ground so far as the Society should act; and the report was accepted and adopted.

In the matter of the proposition from the Nebraska State Medical Society for the appointment of an interstate medical representation, a committee reported that the Massachusetts Society accede to the proposition, and Dr. Bowen, of Platte City, Nebraska, was appointed as the representative of Massachusetts there.

The first medical paper of the session was on "Cremation in its Sanitary Aspects," by John O. Marble, M.D., of Worcester.

The reader set forth in a striking manner the danger in which the living are placed by the burial of the dead, and cited numerous authorities, both native and foreign, to show this. Earth burial, he claimed, affects not only the ground itself, but the water also, while cremation is liable to none of these objections.

Other papers were read as follows: "Diagnosis and Treatment of Occipito-posterior Positions," by William L. Richardson, M.D., of Boston. He dwelt upon the value of external palpation in the diagnosis of fetal positions, and described the method. He then showed his method of applying a forceps designed for flexing the head when unduly extended in occipito-posterior positions. "The Influence of Ovariectomy on Surgery" was the title of a paper by John Homans, M.D., of Boston, in which the progress of the operation was traced in a very interesting manner from its first performance, in 1809, and its relation to other abdominal operations shown.

The following delegates were then presented: A. B. Worthington, M.D., of the Connecticut Medical Society; Peter Foley, M.D., and W. L. Bates, M.D., of the New York Medical Society; E. S. Abbe, M.D., of the Vermont, and C. R. Walker, M.D., of the New Hampshire Medical Societies.

A brief intermission followed, during which the Fellows had an opportunity for pleasant social greetings, and to visit the exhibition of apparatus already described. As usual the manufacturing pharmacists occupied rooms at the Brunswick Hotel where they displayed their products to all visitors, and where a "free dispensary" seemed to be well patronized.

#### ANNUAL DISCOURSE.

At 12 o'clock the Society reassembled to listen to the annual discourse by Franklin K. Paddock, M.D., of Pittsfield, on Antiseptic Surgery, which is published in full in the JOURNAL.

#### THE DINNER.

At the conclusion of Dr. Paddock's address, a vote of thanks was adopted, and the Society adjourned to meet at 12.30 P.M., October 7th. Then in accordance with the usual custom the Fellows were called in order of seniority, and preceded by the officers and invited guests marched to the skating-rink in Clarendon Street. The entrance this year was from the rear of the hall so that late comers and early goers were not so likely to disturb the proceedings. For the first time in the history of the Society the banquet hall was graced by the presence of the fairer sex—Female Fellows, shall we call them? The platform was at the northerly end of the building and was carried further out toward the centre of the room than last year. The orchestra was stationed in the gallery opposite and discoursed sweet music which was only occasionally broken in upon by the screech of a locomotive on the tracks outside. Some 800 Fellows found room at the tables, after which Dr. ROBERT AMORY, the anniversary chairman, called the assembly to order, while the divine blessing was invoked by the Rev. William Lawrence, Professor in the Cambridge Theological School. At the right of the chairman sat the President of the Society, and at the left His Honor the Mayor of Boston.

Among the other guests of note beside the officers of the Society were Dr. Henry W. Williams, Dr. H. P. Walcott, Hon. F. T. Greenhalge, of Lowell, Dr. Alfred Hosmer, Dr. H. I. Bowditch, Professor John Trowbridge, of Harvard College, Hon. E. I. Thomas, of Brookline, Hon. George A. Marden, of Lowell, Dr. F. K. Paddock, Dr. F. R. Sturgis, of New York, Dr. E. C. Seguin, of New York, ex-Surgeon-General Dale, Surgeon-General Holt, Dr. Samuel A. Green, Dr. B. E. Cotting, Mr. Thomas C. Amory, Dr. George H. Lyman, Dr. Charles F. Folsom, Dr. W. L. Richardson, Dr. St. John Roosa, of New York, the Rev. A. Amory, Dr. Gilman Kimball, Dr. George B. Shattuck, Dr. A. L. Mason, Dr. George C. Shattuck, Dr. Samuel H. Durgin, Col. Charles H. Taylor, Mr. James C. Fiske, of Cambridge, Mr. Arthur Lincoln, and others.

When the tables were cleared and the cigars lighted, Dr. Amory introduced the speaking as follows:—

FELLOWS OF THE MASSACHUSETTS MEDICAL SOCIETY.—It is my pleasant duty to welcome you all to this annual feast. The custom which is continued in this eighty-fourth anniversary dinner probably unites us more closely and fosters our prosperity.

Momentous questions discussed from time to time in our business meetings seemed liable to leave permanent marks and to jeopard our organization; but in a few hours the bitterness of debate was consumed with the food upon the tables, and scars erased before we met again to discuss other matters of similar portent in other or subsequent years.

We have seen other societies which did not think it necessary to follow our example totter and fall to pieces over matters no more serious than those which we have grasped.

No code of ethics, no question about the sex of candidates seeking for admission, no wrangle about

the 'pathies evanescent as the day, no fight over who shall be our officers has ever shaken the foundations of our organization. We, as a Society, still live and are proud of our fellowship.

During a period of a few years some of our misguided members chose to adopt dogmas of cure which most of us considered foolish and untrustworthy. These men were so few in number and so little known to science or literature that we paid but slight attention to them or their new-fangled notions. While admitting their privilege to hold erroneous tenets, it was not until called upon by others outside of this Society that we impeached these members and dropped them from our rolls. In spite of these experiences, and others like them, our grand old conservative Massachusetts Medical Society still goes through the troubled waters, with prow to the seas, ever onward and ever onward; if an occasional wave comes aboard she shakes herself free and presses forward with steady progress. We occasionally look astern and see shipwreck and disaster overtake those swift-going crafts which chose to leave our stalwart vessel.

Again I say, all honor to our Society which braves the storms and holds fast to the grand old arts of cure and to the knowledge of the natural laws of disease. Let the individual try the experiments of new theories and the Society will prove the work and honor the workers.

It is not the duty of the presiding officer of this social occasion to offer you an address, but simply to introduce those who can perform this pleasant work more gracefully. But before calling upon those who are ready speakers and who bid you remember that "brevity is the soul of wit" I must ask you to join in a toast to our Massachusetts Medical Society, founded by men of learning and of distinction, and fostered by their successors, among whom are associated men of literary fame, men of erudition, men of wisdom, men of culture, men of skill, and to whose ranks of 1,500 Fellows it is an honor to belong. I call upon your President, Dr. Charles D. Homans, to verify my statement and to respond to this toast.

The PRESIDENT, DR. HOMANS, arose and, being very cordially received, said:—

MR. CHAIRMAN AND GENTLEMEN, — So many times has this anniversary dinner been held, and so many times has the President answered to this toast, that I certainly cannot expect to find anything to say which has not been much better said before. I congratulate you on the healthy condition of the Society. If the old saying be true "happy is the nation which has no history," how much more happy is it for a medical Society as large as this, when its executive officer can say, as I can to-day, that nothing has occurred during the past year and there is no report to make. Since the last anniversary, ten or fifteen women have satisfactorily passed the examination of the Board of Censors in their several districts and have been admitted to the Society. I have offered them the right hand of fellowship whenever I have had an opportunity, and am sure that every gentleman connected with this ancient Society will do all in his power to render everything agreeable and pleasant to them, so that all, both men and women, shall equally enjoy the privileges pertaining to member-

ship, and be equally amenable to the laws made to regulate the conduct of those belonging to the Society.

While attending the meetings of the several district Societies in different parts of the State, I have been frequently told by members that they are very much discouraged by the great success of quacks, and they do not see the use of belonging to the Society, as it cannot protect them from the disagreeable results of this state of things. Now it is true that quackery hardly ever has been so rampant as at present. There is in Massachusetts no law against the practice of medicine by any person, however ignorant, and as there are such laws in some of the neighboring States, the irregular practitioners seek refuge here in great numbers. But this class of persons has always existed and always will exist, though possibly much may be done by a proper law to modify their present successful career. In 1828 the late Dr. George Shattuck, a former President of this Society, and a very shrewd and sensible man, said, in a letter in my possession, that at that time he estimated that one sixth of the population of Boston were under the treatment of Thompson and his followers, who had formed a botanical society, his system of practice being by hot drops, sweating, etc. How is it now with this so-called system? At the present time his disciples have nearly all disappeared from the medical world, while the very name of their master is almost unknown to the present generation. Perhaps it will be so by-and-by with another class of practitioners who at the present time occupy in the city of Boston about the same relative position that the followers of Thompson did sixty years ago!

But history repeats itself: the Thompsonian system, Perkins's "tractors," the so-called "mind cure," nay, even Lydia Pinkham herself, must in turn yield to other claimants on the credulity and imagination of mankind, and you must all bear in mind that, notwithstanding all this prevalence of quackery, the Massachusetts Medical Society has gone on increasing in numbers and influence, and while acknowledging no blind allegiance to any system, and holding itself ever ready to learn from all, "it pursues the even tenor of its way" with dignity and self-reliance. I beg you, therefore, to have faith in yourselves, in the Society, and in the principles which you represent.

The next toast was "To the good Old Commonwealth of Massachusetts, sturdy and sound, may she ever stand in the foremost ranks of her sister States; and may the execution of her laws which so largely deal with the public health and ever promote the public wealth be entrusted to safe hands."

A letter was read from His Excellency Governor Robinson, expressing his regret that numerous and pressing engagements prevented his acceptance of the invitation to dinner with the Society. The chairman said: "As His Excellency is unable to be present, I call upon one who, as Chairman of the Health Committee of the State Board of Health, Lunacy, and Charity, has ever been true to the best interests of the people,—Dr. Walcott,—to respond to this toast."

DR. WALCOTT, whose recent experiences at the hands of the politicians were fresh in the minds and

sympathies of all present, was received with great enthusiasm which showed itself by repeated cheers and applause. He said: Not now a member of the State Board of Health, Lunacy, and Charity, and having no claim to personally present the views of His Excellency the Governor, I should be placed in a position of great embarrassment were it not that this unexpected, almost overwhelming reception, on the part of the body of men most competent to fairly appreciate the services I may have rendered the State, makes it proper for me to say a few words about the organization with which I have been for some years connected.

The history of the old State Board of Health I need not repeat; the men composing it, the work accomplished for the protection of the public health cannot be forgotten.

The present conglomerate Board had its origin in relations purely personal and political, as a number of the ablest men of the old organization had entered the new. Much good work was done, however, but un congenial associates, needless sacrifices of thought and time drove one good man after the other from his place, until in this present year we find a Board so constituted that but two of the nine members are practitioners of medicine, and the important functions of a commission in lunacy are performed under the direction of a committee, not one member of which could be fairly reckoned as an expert in diseases of the mind.

There is, however, even with this disagreeable side of the question, a certain satisfaction to me as more intimately concerned with the Health Department of the Board in knowing that in these later years, even, we have secured the enactment of laws for the prevention of the adulteration of food and drugs, and that Massachusetts is to-day the only State in the Union where such laws have been enforced for a succession of years.

In regard to the merely personal element in this reception, I wish to say that it was the belief that I had the approval of the medical profession that led me to accept and almost compelled me to retain a position in many ways disagreeable. For a better reason yet I am thankful for this expression of feeling. The position of my successor will be strengthened by the knowledge that my poor endeavors have had from you this all-sufficient reward.

There is every reason to assume that some member of this Society will be selected to fill the vacant place and I can have no doubt that he will be competent to deal with the questions that affect the public health and will receive in his turn the applause which now fills me with wonder and content.

The CHAIRMAN said: We are pleased to remember that we have guests here wholive in the great metropolis of the new world, in a city more than twice as large as ours and, I might say, more than twice as dirty; and if dirt brings disease she should need four times as many doctors. Whether this be true or not makes little matter to us now, since its discussion must be confined to this end of the hall, from which we propose to do most of the talking and you the hearing. I take pleasure in introducing, as the next speaker, Dr. St. John Roosa, of New York, and I have no doubt you will lend him your ears."

DR. ROOSA said that, notwithstanding the dubious compliment implied in his introduction, he counted it a rare privilege to stand in this presence; there was a time when New York was clean, but that was before the Yankee invasion, before the Knickerbockers gave up to the invaders, who have gone on from one thing to another until they have set up the statue of a pilgrim in Central Park, and we are almost ashamed to own that we ever had anything to do with Peter Stuyvesant. He came from the Medical Society of the State of New York, not as a delegate, but in his own personal capacity. In his Society there has been something of a commotion, but it has fought the fight and peace has been declared. A new organization, composed of men who yet retain their membership in the only chartered Society, has been formed, but the old Society, with its ranks intact, still holds up its banner in favor of education, and for the good of the people whom it serves. By it the question of consultation has been left to the circumstances of the case, which determine when and where the practitioner shall go. With the American Medical Association the New York Society has no quarrel, but that Association cannot legislate for the needs of all the societies of the United States. In the opinion of many it should be a national convention, but instead of that, meeting in remote sections, and dominated by the influence of the section where it happens to be, it attempts in vain to discipline State organizations. It should at once relegate to each State association all matters relating to its own constitution and code of ethics. The great question in New York is not the matter of consultation with homeopaths, but how it is possible to so elevate the standard of medical education that allopaths and homeopaths and hydropaths shall be unknown. And we think this can be reached by a Board of Examiners entirely independent of the teaching members of the profession. If we succeed in educating men up to the standard of the Army and Navy Board quackery will perish from the land, and all the 'pathies will meet with the same fate. His message to Massachusetts was to ask it to stand by New York in that advancing column which is to overthrow quackery by placing the medical profession on the plane of the other learned professions; with such union this result can be brought about, and in medical education this country will command the respect of the world.

DR. HENRY W. WILLIAMS, of Boston, was introduced as an ex-President of the Society and was warmly received. He said that he thought that all will admit that the eye ranks next the brain; the eye is the brain's most important minister. Since the last meeting the eye has again come to the front. Dr. Koller, of Vienna, now no longer unknown to fame, modestly announced last September that having seen it recorded that cocaine caused a state of anesthesia on being applied to the tip of the tongue, he had used it for a similar purpose on the conjunctiva and found that by its application the sensibility of the eye can be suspended so that operations can be performed upon it without producing general unconsciousness or deleterious effects.

The same action has been found to extend to all the mucous membranes. Since ether was first suc-

cessfully used (near where we now stand) to induce anesthesia, no greater boon has been given to the world than cocaine. The speaker eulogized that specialism which, by steady application to its chosen field of work, can make a discovery like this, and then give its benefit freely for the use of suffering humanity. He thought it highly fitting on such an occasion as this to make mention of a remedy which, with increasing plentifulness of supply, is destined to be of such great service in surgical science.

The HON. FREDERICK T. GREENHALGHE, of Lowell, was introduced as one of our wise legislators and a brilliant member of the bar, who could tell why the Massachusetts Legislature thinks the pharmacist should be an educated professional, and why the public should be protected from uneducated apothecaries, and perhaps, also, whether it should be protected from the charlatan, the quack, or the uneducated physician.

Mr. Greenhalghe said he did not see why at this particular juncture, when the House of Representatives is staggering in a fit of epileptic convulsions, he should be named as a member of that body. He told, in a pleasant way, how through all the storm and disturbance the Pharmacy bill, "breathing Sabeian odors from the spicy shores of Araby the Blest," rode triumphantly and is now safely anchored in port. The "doctors'" bill is in the offing. Now there is a popular prejudice against a doctor's bill, and whether it will or will not meet the good fate of the Pharmacy bill it is not now possible to determine. Coming hither he met an undertaker out for a holiday: therefore he expected to meet a majority of the medical profession. We lawyers know you chiefly as experts, and your testimony often enables us to win a case when nothing else would; when both the law and the facts are against us, there is no such panacea as a medical expert witness. When a case is in a moribund state we call in the doctor. There is no success to be compared with that of an expert with a "hypothetical case." If you could only confine your practice to hypothetical cases how the mortality rate would fall! We have another tie of sympathy; we, too, are treated with ingratitude. I was glad to hear your reception of the honored name of Walcott. After all, there is no cause for surprise at his defeat, for we know that often the only reward of standing firm for truth and right and justice is crucifixion. You deal with the bodies of men and we with their consciences, and we both do it pretty effectually. The clergyman near me might take exception to part of this remark as an infringement on his grounds, but the clergy are under a cloud and they are trying to regain their prestige by taking up the faith cure. The doctor, the lawyer, and I will add the clergyman, are the most trusted and respected members of the community, and it is their duty to take with good nature the badinage and raillery of the ignorant. Sir Thomas Brown said that the fabric of man had certainly a trace of divinity, which was before the elements and owes no homage to the sun. The Scripture tells us that the bodies of men are the temple of God. In that temple we are all reverent workers.

The CHAIRMAN said: We meet in a city which

thrives and prospers and grows on land and sea, but though she cannot find room enough upon the natural land to build her houses and streets, yet forfeits large portions of her territory for public parks, and that without stint.

We have invited to our feast its chief magistrate to whose management has lately been entrusted large powers over her temporal affairs. I take pleasure in calling upon our guest His Honor the Mayor to respond to the toast to the City of Boston.

HIS HONOR, MAYOR O'BRIEN, responded: He said it required courage to make even a brief speech in such a presence. Boston was honored by the gathering of so many distinguished men. He spoke of the city's public institutions for the treatment of the sick, and gave some of the expenditures upon them showing that with a reduced tax-list for this year, the appropriations for the Board of Health, the Health Department, and the City Hospital were greater than for the previous year. Boston is called a cold place, yet if you meet an accident in her streets you are taken to the hospital where the best surgical skill of the country is at your free command. The city has cleaner streets and is soon to have finer parks than any city in the world. The Charles River improvement will be one of the most magnificent improvements ever carried out, extending six miles up on one bank of the river and as far down on the other. It will cost much money and much time and we may not all live to see it completed, but it will be done.

The statistics of the deaths from smallpox were given for the last forty-five years. In the decade ending in 1850 there were 457; in that ending in 1860, 762; from 1860 to 1870, 630; for the four years 1870-73, 1,100. For the eleven years, 1874-85, only 26. This is the magnificent work of the Board of Health. The mayor felt it to be his first duty on his inauguration to call together the leading physicians to consult with the Board of Health. The services of the whole 700 police of Boston were placed at their disposal to abate nuisances and he felt that Boston was to-day better prepared for cholera than ever before in her history.

The HON. GEORGE A. MARDEN, of the Massachusetts Senate, responded to the following introduction by the Chairman:—

"I requested the Hon. Senator Marden to be present at this dinner and to address you gentlemen of this Society. He replied that he would be pleased to do so, unless he went fishing. Fortunately for us work on the bill has kept him in our city, and here he is to tell us what he would rather do than go a-fishing."

Mr. Marden humorously mentioned a number of things he would rather do than go a-fishing, including making a speech.

"If the 'doctors'" bill reaches the Senate," said he, "it will be passed by that body without a four-days' convulsion over it. Prejudice against that measure is unreasonable."

Speaking of doctors' bills he was reminded of an old lady in Maine, whose husband had a long illness and died. A year afterward the doctor's bill came in and was unheeded. Finally when the physician felt obliged to press for his money, she brandished her broom in his face and said: "I want you to

understand you don't get a cent out of me till I've paid my honest debts."

Another thing he would rather do than go a-fishing is to eat dinner. To eat one's dinner with a thousand doctors is not a common experience; but perhaps behind that dinner lies the expectation of increased practice. My friend from Lowell, he said, has spoken for the lawyer, the doctor, and the clergyman incidentally; but he has forgotten the important estate—that of the journalist. When the doctor's patient is dead, and the lawyer has set up the will, and the clergyman preached the sermon, the journalist comes in and writes the obituary, covers up the imperfections of your work, eulogizes your victim, and smooths everything decently over. The speaker alluded to the warm reception tendered Dr. Walcott and said he was struck by the doctors' loyalty to each other, and was certain that Dr. Walcott had added to his honors by getting away from that composite body, the Board of Health, Lunacy, and Charity. Some time the State will have a Board of Health that is a Board of Health and not a piece of political patchwork.

COL. CHARLES H. TAYLOR, of the *Daily Globe*, was presented as a young man who for years had sat at the reporter's table and reported the proceedings of the Society, but who now sits at the editor's table and to-day at this board. He responded pleasantly for the daily press, and said that if he has succeeded in life it is partly because of the mental friction of attempting to report the meetings of the Society. One might infer from the newspapers that every one was cured by patent medicines or by faith, but you have a flourishing Society, and it occurs to me that those people have been making more noise than cures. It is certain that your Society holds the confidence of the community, and it does it by its intelligence and its fidelity to duty. It seems to me there is something in the mind cure, but there is nothing new in it, and the cheerful physician uses all there is of it. The press has a mission; it is to cultivate the good and the beautiful. If it has any fault at all it is lack of assurance, of self-assertion. It is to be the corrector of all evils. Incidentally it is to make money. In this last respect your profession is like ours. We have the kindest feelings toward you. Through an imperfection in your constitution as a Society, you cannot advertise with us, but you help new subscribers into the world and keep old ones in it.

At about half-past three the festivities were brought to a close with "Auld Lang Syne" by the orchestra, and the Fellows dispersed.

#### BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

L. M. ROCKINGHAM, M.D., SECRETARY.

MAY 25, 1885. The President, Dr. F. W. DRAPER, in the chair.

#### DEMONSTRATION OF THE POSITION AND LENGTH OF THE SIGMOID FLEXURE OF THE COLON; AND HOUNSTON'S VALVES OF THE RECTUM.

DR. W. J. OTIS demonstrated, by means of a dissection recently prepared by him at the Harvard

Medical School, that the sigmoid flexure of the colon was that position of the gut between the lower end of the descending colon and the beginning of the rectum. He called attention to the fact that in this case the descending colon ended just in front of the psoas muscle, and the rectum began just below the promontory of the sacrum; that the distance between these two fixed points was only two inches; that the intervening loop of bowel when spread out measured just two feet; that the meso-colon of this loop measured in the longest part four inches; that the position of this loop when empty, or only moderately distended, was entirely within the cavity of the true pelvis, and not in the left iliac fossa; that it presented no resemblance to the letter S when empty, but did when fully distended.

Dr. Otis next demonstrated, by means of Codman and Shurtleff's small electric light, the folds of the mucous membrane of the rectum known as Houston's valves, and Kohlrusch's *plica transversalis*. These folds were three in number, semi-lunar in shape, and projected from one half an inch to one and one-half inch into the lumen of the gut, and were plainly seen through the dilated anus and a hole trephined through the sacrum into the rectum. The lowest fold was placed on the left side, extending from the prostate to the coccyx. The middle fold was placed higher up, on the right side, extending from the base of the bladder to the fourth bone of the sacrum. The uppermost fold, the smallest of the three, is placed on the left side extending obliquely from above downward, from the second bone of the sacrum to a point anteriorly about an inch above the middle fold. Dr. Otis said that he had observed these folds in five dissecting-room subjects, three males and two females; that their relation to each other was apt to vary, but in every case there were two folds on the left and one between them on the right; that the latter was always the largest and most prominent of the three, the "*plica transversalis*" of Kohlrusch. The best position to place the subject was the knee chest, then dilate the anus, or divide it posteriorly to the tip of the coccyx and stitch each flap back out of the way to the skin of the buttock; then with the aid of a Sims's speculum, a head mirror, or, better still, a small electric light, and a blunt hook, the folds will be readily seen.

DR. W. C. B. FIFIELD said that the position of the sigmoid flexure of the colon has been long in dispute, and that its different position at different ages has not been fully discussed. The length of its attachment to the mesentery is unsettled. Years ago it was asserted by Huguier, as the result of dissections, that in infant life the sigmoid flexure is not in the left, but in the right, of the pelvic cavity, and that the incision for artificial anus in the groin, a recently revived operation, should always be in the right side. This assertion has proved a stumbling-block to operators who have found clinically that it is only exceptionally true, and who have had to grope for the gut. The speaker thought that he had found the right-side position in one or more dissections of new-born infants.

DR. J. C. WARREN said that he had once done the operation in the right groin in a case where the rectum was absent. He got a large flow of mæconium, but

did not feel sure whether he had tapped the ascending colon or the sigmoid flexure. Death from inanition is stated to be the invariable result of operation in the right groin in adults, owing to the want of absorbing surface. There was, unfortunately, no autopsy.

DR. FIFIELD answered that a woman lived for years at a tavern near Paris who had been operated upon in mature life in the right groin, and who professed herself to be very comfortable.

#### DERMOID CYST OF THE OVARY.

DR. J. W. ELLIOT showed a dermoid cyst of the ovary which he had that day removed by laparotomy. The cyst was about the size of a child's head before it was removed. A pint of fluid had been evacuated which was liquid at the temperature of the body but which caked and looked like lard, after removal. The cyst also contained bunches of hair and pieces of skin.

Before the operation the cyst felt hard and was wedged in the pelvis. The uterus ran obliquely across to the right side and was freely movable. Dr. Elliot had been able to make the diagnosis of a dermoid tumor before the operation.

At the operation the pedicle was found not between the uterus and tumor as usual, but on the outer side of the tumor toward the brim of the pelvis. The tumor had developed from the ovary, growing toward the uterus, crowding the Fallopian tube and ovary out toward the pelvic brim. The tumor was universally adherent and the operation unusually severe, lasting two hours.

DR. F. B. GREENOUGH read a paper entitled

#### CASES OF CEREBRAL SYMPTOMS IN EARLY (SECONDARY) SYPHILIS.<sup>1</sup>

DR. J. C. WHITE said that he did not agree with the reader that cerebral syphilis is a new order of the disease. The poison that causes syphilis undoubtedly acted a thousand years ago as it does to-day; but it is now that we are beginning to recognize these forms of its manifestation which were formerly not attributed to their true source. John Hunter did not recognize them because he was thrown off the track for want of the fundamental knowledge of the preliminary process.

The cases reported, occurring as they did while under treatment, and lacking the graver characteristics of later cases, are probably to be explained by simple inflammation.

Headache, when most severe in the later stage, does not always yield either to small or to large doses of the iodide. Even in the early cases a combination of bromide with iodide of potassium often exerts a more rapid control than iodide alone.

DR. S. G. WEBER said that he had recognized more cases of early cerebral syphilis of late years than formerly. It is possible that he has greater skill in diagnosis. It is possible that he sees more patients, but when he considers the number of dispensary patients that he saw in his early practice the increase cannot be great, and he recognized these cases at that time. He is therefore compelled to believe that he has met more of them within the last five years than was the fact seven or ten years ago. He has been led to use larger doses of the

iodide of late years by finding that he got only partial benefit from smaller ones. Some cases receive ten or fifteen grains, then twenty, then thirty or forty grain doses, three or four times a day, getting relief only when the larger dose is reached. Occasionally small doses will answer, but in severe cases he does not dare to trust to them. He hopes then to speedily affect the disease in order to save life. In very few cases is iodide enough without the addition of mercury. The speaker again called attention to what he believed a fact: that large doses of iodide are sometimes well borne where small ones disagree with the patient.

DR. AXNER POST said he would simply mention two cases of early nervous lesions of an entirely different type from any of Dr. Greenough's cases. Unfortunately he was unable to give the exact time of the disease at which either of them appeared, though both were early enough to be included in the cases mentioned in Dr. Greenough's paper. The first case of cerebral syphilis that he was ever called upon to treat occurred in a sailor who was under treatment for an early syphilitic eruption. While under treatment his stomach refused to retain anything, he became dull and heavy, and in the course of a very few days was completely comatose. He lay in this state for a number of days; was nourished and medicated principally by the rectum, and gradually regained consciousness. After leaving the Marine Hospital, in which he was a patient, he spent quite a time in the almshouse and reported to Dr. Post, after some months, apparently well.

The second case was a young woman who was first seen on September 11, 1882. She then had an abundant papular eruption and mucous patches. The eruption had existed for some time, but was the first appearance of general symptoms. The data in regard to the primary sore could not be exactly determined. She improved rapidly under treatment. On November 12th her eruption had reappeared, and she was suffering from a pain in the head, which was of great intensity, and had nocturnal exacerbations. It was accompanied by vomiting, pain down the spine and in the shoulders, and was exceedingly obstinate to treatment, but finally yielded to iodide of potash and inunctions. In December she had an iritis. On January 31, 1884, Dr. Post was summoned, to find her in bed in a maniacal condition, her delirium resembling that of delirium tremens. She saw all sorts of horrible objects, failed to recognize her nearest relatives, and was said to have convulsive attacks at night. Combined with it was great muscular weakness and some inability to fully control her muscular movements. It was several weeks before she was able to recognize her friends or became perfectly rational, and even longer before she regained perfect control over locomotion. After she was able to walk, as far as strength was concerned, she was unable to walk straight toward a given object, and she often tottered in a manner to make the spectators expect her to fall. Her recovery was perfect, and she still appears to be in good health, though definite information in regard to her condition is wanting.

DR. EDWARD WIGGLESWORTH was of the opinion that nervous manifestations of syphilis are becoming more common, not that the anatomical changes are

<sup>1</sup> See pp. 571 and 595.

different, but that the changed habits of modern life predispose the nervous system to be easily disturbed, as it is by non-syphilitic causes as well. He must confess, however, that his own worst cases had happened to be in vigorous, phlegmatic people. In treatment he would not forget that it is a degenerative disease with which he has to do, but would combine tonics with specifics. The speaker agreed with Dr. Greenough that moderate doses of iodide are often enough in dealing with the early forms, but he also agreed with Dr. Webber that in the late forms large ones are more often needed. He quoted a case of Dr. Taylor's treated with two ounces daily before getting the desired effect. He had himself got results from two hundred and fifty to three hundred grains that he had not had from smaller doses in the same patients.

DR. FIFIELD said that he thought that absolute delirium, as in Dr. Post's case, must be very rare. He did not remember having ever seen a case. Others had been reported, however, and he mentioned a case of Fournier's where a man probably began to have hallucinations while returning from a drive. It is possible that cerebral symptoms may sometimes depend on syphilitic kidney, and the speaker related a case that he thought was explainable in that way.

DR. J. J. PUTMAN said that while small doses of iodide are often enough, yet that large doses are sometimes absolutely necessary. He also called attention to a kind of irritability and to insomnia as early cerebral symptoms.

DR. GEO. H. LYMAN thought that we are hardly justified in giving small doses in a disease that may end so disastrously. In giving large doses of the iodide it should be combined with a tonic, and he thought that iron was preferable to anything else.

DR. R. M. HODGES said that if syphilis is in some respects milder than formerly, yet that an increase in cerebral symptoms is certainly an exception, and from it we ought to learn the lesson to protract the treatment. When a mild eruption has disappeared, the patient and sometimes the physician are apt to think that continued treatment is not worth the trouble, but it would be better to continue treatment to the end of one's days than to run the risk of such complications.

DR. WHITE said in reply that he had seen grave symptoms appear after two years of continuous treatment.

DR. HODGES did not suppose that the disease would be always stopped in that way, but that its severity would be diminished.

#### TANNATE OF MERCURY.

DR. G. H. TILDEN showed a specimen of the tannate of mercury which has recently been employed in the treatment of syphilis, having been first used for this purpose by Lustgarten. The drug consists of a coarse granular powder, of a greenish color, inert and tasteless. It is unaffected by acid solutions, but is decomposed by dilute solutions of the alkalis, the action of which causes the formation of mercury in a very finely divided state, a fact which can be verified by the microscope. The theory of its action is that it passes through the stomach, when the secretions are acid, unchanged

until it reaches the intestine, when the normally alkaline secretions cause its decomposition and the metallic mercury, which is set free, is absorbed. The reports of its efficacy in the treatment of syphilis are very favorable, and its use is apparently attended with uncommon freedom from any of the ordinary bad effects due to the administration of mercury, such as salivation and gastric or intestinal irritation. The dose is about a grain, and it should not be combined with alkalis or the iodide of potash, the former causing its premature decomposition, while the latter combines with it to produce the iodide of mercury, a much more irritating and powerful preparation than the tannate.

#### STILLINGIA.

DR. V. Y. BOWDITCH asked if any one knew anything about stillingia.

DR. WIGGLESWORTH answered that it is an utter humbug. The question being asked of a large number of specialists, it was found that of those who had tried it, all, without exception, had found it of no value.

DR. LYMAN asked how the reader would draw the line between nervous symptoms and cerebral syphilis.

DR. GREENOUGH said that headache alone did not show actual cerebral lesions, either neoplasms or simply inflammation, but when we get even quite pointed paralytic symptoms, we can conclude that some trouble of the cerebrum exists.

In all five of the cases reported there were decided symptoms of partial paralysis, besides the persistent headaches. In three cases, partial hemiplegia; in the other two, difficulty of articulation, stumbling, etc. While he considered such symptoms in early syphilis as rare, the severe specific cephalalgia was comparatively common. He had seen many cases where the headache of the well-marked syphilitic type was very severe that went no farther. In some cases this result was undoubtedly due to treatment; in others the headaches ceased without further complications where proper treatment had not been followed. While he considered that one of the most important practical deductions to be drawn from the consideration of these cases was the imperative call for the administration of the iodide of potassium, he did not think that we should be justified in calling a case one of cerebral syphilis, in which the only symptom was severe headaches.

#### CONNECTICUT MEDICAL SOCIETY. NINETY-FOURTH ANNUAL CONVENTION.

The Ninety-fourth Annual Convention of this Society was held at Hartford on May 27th and 28th. The meetings are held alternately at Hartford and New Haven. Last year an attempt was made to establish Bridgeport as a third regular meeting-place, but it found little support outside of Fairfield County. Of late years the Hartford meetings have been held at the City Hall, which, though very convenient in situation, has proved unsatisfactory in some other respects, and the change was universally approved of having the assembly at the Superior Court Room of the new County Court House. This

building, of which the county may justly be proud, was the theme of much favorable comment, and the accommodations for the Society were all that could be required.

In Connecticut, the *business* of the Society — which in every organization is practically settled by committees — is put into the hands of a large committee of about fifty members, called Fellows, who are elected by the various County Societies at their meetings held previously. In this way the founders of the Society endeavored to secure an equable geographical distribution of the governing body throughout the State; guarding against the "packing" of the house by the members from any particular section. All other members have a right to be present and to take part in debates — all rights, in short, except that of *voting*, which they are supposed to do by proxy through the representative Fellows. The main interest of the business meeting this year centred about a proposition to do away with this time-honored arrangement and substitute one by which all members should participate as Fellows or principals. The separation of the State Society from its union with the Medical Department of Yale College, which had continued since 1810, seemed to present an opportunity for further changes, and this was brought forward in the shape of a proposed new charter, the special features of which were (1) the reorganization, as above alluded to, and (2) the appointing of a committee to examine candidates for a degree and license them if found satisfactory. The licensing of candidates was a privilege voluntarily surrendered by the Society at the time of its union with the Yale Medical School, and now that that union has been dissolved (by a vote of the Society last year, confirmed by Legislative acts during the past winter) the question arose: Is it best for the Society to resume, even technically, the power of granting degrees? It seemed to be admitted by all that the occasions for granting degrees would be very few and perhaps the Society would never exercise the right, but the advocates of it said there was no harm in resuming the privilege, which if not taken now would never be attainable. The opponents stood out boldly in the name of medical reform. "Too many 'doctor-mills' already," said they. "Any man who is fit to be a doctor can go through a medical college and get his diploma, and moreover," said they, "if we keep the right of granting degrees we can never go before the Legislature and ask that the eclectics, homeopaths, etc. shall not be allowed to exercise it." On the one hand there seemed to be a strong desire to nip in the bud this revolutionary charter, and on the other an impression that perhaps it would be better to postpone action till the next meeting, and the latter course was pursued, though the vote for postponement was carried by a bare majority of two. The President, in his address to the Fellows, urged that this subject, which had been previously brought up at a special meeting of the Fellows in January, be finally disposed of, but the Society ordered otherwise, and the bone of contention remains.

The exercises of the first day consisted in the appointment of the usual committees, reading of the Treasurer's report and receiving the reports of

various committees, none of which were of any interest to the general medical public, except those giving rise to the discussions above alluded to. The second day's exercises began at half-past nine, and were introduced by the Secretary's report, by Dr. St. John, of Hartford: "The net gain in members is fifteen and the total membership 196. Eight deaths are reported — twice as many as last year. In the death of Dr. Chamberlain, our late Secretary, the Society loses an active, intelligent worker; a man of remarkable executive ability; one devoted to the work of building up and strengthening this Society."

The President, Dr. B. N. COMINGS, of New Britain, then delivered the annual address to the Society, his subject being "Nervousness," which he described as a condition rather than a disease, and considered that in New England unusually good facilities existed for studying the phenomena. The intensity of life, the competition and restlessness of New England, make it the home of the most nervous people on the face of the earth. He did not propose to discuss nervousness as the result of organic disease, but "in an unscientific and practical way to call attention to the extremely nervous condition of a large percentage of New England people, and consider the cause. All medical men testify to the rapid and universal increase of nervousness. According to the reports of institutions for the insane the cause is unknown in more than forty per cent.; it is a condition that comes about from a great variety of causes that are not dependent on any organic lesion. A great portion of our nervous patients are not insane but live very close to insanity at times, and in paroxysms of high excitement bear a close resemblance to lunatics. The New Englander exhibits his characteristic nervousness in the way he takes his vacation — rushing through Europe as if he had taken a contract to 'do' the Continent in thirty days. It is becoming more and more a characteristic of all persons whose health is generally below par and complicates unpleasantly the symptoms of many real diseases. The cause is often to be found in heredity, and as New England stock is rapidly deteriorating and moving out, this is acting more powerfully. The children of great brain-workers are often below than above mediocrity — our best men generally come from sound stock in rather humble life, a percentage of good physical organization, strong common sense, industrious habits, fair intelligence, and a life free from excitement.

"Overpressure in schools is a prolific cause of nervousness. The speaker had sent out circulars and gathered instructive statistics regarding the habits, study out of school hours, dreaming about studies, etc. Fully one third of the children in Connecticut in the graded schools suffer seriously from overwork in study, become nervous and irritable at home, lose appetite, and run down in term time. Everything tending to overwork or unnecessary excitement should be pruned out. This necessitates giving up two factors now deemed essential, namely, competition and marking. With children under twelve one half of the time now devoted to study should be given to physical labor or training." The speaker concluded by alluding to noted men like Lincoln, Garfield, and Burritt, who acquired

their education with a very large admixture of physical labor thrown in. The address, which was quite long, was received with marked attention, and a resolution was passed endorsing the opinions expressed regarding the evils of overpressure in schools. We learn that a portion of the paper is to be republished as an educational pamphlet. The Committee on Matters of Professional Interest made, through the chairman, Dr. Wordin, of Bridgeport, an extremely interesting report. The usual plan of the committee has been to collect miscellaneous material sent in by county reporters and endeavor to arrange it so as to present it intelligently. This year the committee endeavored to guide investigation and stimulate experimentation with new remedies, and to that end issued circulars last summer asking the members to try in appropriate cases *cascara sagrada*, *convallaria*, and *psicidia*. The tabulation of the reports received leads to the following conclusions: *Cascara sagrada* is universally conceded to be a valuable remedy for habitual constipation, especially in old people. In strong doses it is cathartic. *Convallaria* was found to be a useful substitute for digitalis in many cases, and in some superior to it. *Psicidia* had been frequently substituted for opium and was found to be free from some of the disadvantages of the latter drug. The committee was aided by an enthusiastic professor and some earnest students who had carried out experiments with these drugs on their own persons and made careful and complete notes of the effects. Of course cocaine could not be entirely ignored and the usual tribute was paid to its virtues, especially in the domain of ophthalmic surgery.

The committee also brought forward the subject of medical education, calling attention to the solid work done in the classes at the Yale Medical School whose aim is not to graduate large classes but to educate men in the fundamental principles of medical science. The system of medical instruction as now pursued in most of the schools is a relic of the past and should give way to the more exacting demands of a later day. The profession of medicine is made too cheap by the 'grab system.' We are oppressed to-day by cheap periodicals, cheap condensations, compends, and dictionaries, to learn the science of medicine. "The remedies suggested were, first, endowments to make salaries secure, and second, to prevent by law the entrance of the unlearned into our medical schools.

DRS. J. M. BROWN, of New Hampshire, MUNSSELL, of Massachusetts, WYLLIE, of New Jersey, FAIRHAM and HUTCHINSON, of Rhode Island, delegates from their respective States, were introduced to the Society by the President and made pleasant and suggestive speeches in response.

Several surgical cases were detailed by Dr. W. C. WILL, of Sandy Hook, most of the operations having been done under antiseptic precautions, the spray being used rather to charge the atmosphere, than to play directly upon the wound. In one case of traumatic tetanus chloral was given in sixty-grain doses at short intervals, chloroform being used to a certain extent also, the case recovering in about a week, and more than six ounces of chloral being used.

A very lengthy and elaborate essay, entitled "Are

there any Symptoms or Criteria by which we may Diagnose Insanity?" was read by Dr. Cassidy, of Norwich. It bore the marks of much research into psychological literature and much ingenuity in collecting and arranging established *dicta* in this field. The author sums up as follows: *First*. The intellect depends entirely upon the senses and the imagination for the presentation of all the objects of its thoughts and ideas. *Second*. There are two conditions of the brain that may produce insanity: (1) organic changes, permanent and easily recognized; (2) changes in nutrition, which may be temporary, producing insane mental action. *Third*. The symptom of insane mental action is delusion. *Fourth*. There is no moral or other insanity independent of the intellect unless there is lack of brain matter, and then the intellect and will are barely discernible. *Fifth*. There is no insanity of the will with sane intellect. *Sixth*. Crime, no matter how often repeated, is not of itself a symptom of insanity, but rather of depravity. *Seventh*. Passion or impulse, however irresistible it may appear, is not insanity and should not excuse from punishment. *Eighth*. There is such a disease as monomania, during which a person may be insane on one or more subjects and perfectly sane on all other subjects.

The length of the preceding papers was so great that several interesting papers which were to be read could not be reached and had to be read by title. They are as follows: "Internal Use of Germicides," by Dr. Knight, of Hartford; "Treatment of Stricture of the Urethra," by Dr. Whittemore, of New Haven; "Angina Pectoris," by Dr. Turner, of Chester; "Centennial Observations on the Past, Present, and Future of the Connecticut Medical Society," by Dr. S. G. Hubbard, of New Haven.

A resolution limiting future essays read before the Society to thirty minutes, and discussion thereon to five minutes for each participant, was adopted. This will prevent in the future any such monopoly of the time as occurred this year, but it would be well to consider the expediency of prolonging the time for reading essays. To hear the Secretary's report, the President's annual address, the report of the Committee on Matters of Professional Interest, receive delegates from other societies, hear reports from delegates to other societies, cases of interest and miscellaneous business, between 9 and 1.30, and have much time left for dissertation and essays, even if restricted to thirty minutes each, seems to us a somewhat difficult problem to solve. We do not see why the evening intervening between the afternoon and morning session might not be utilized. To be sure it was utilized this year, and very pleasantly too, but not exactly in a scientific manner. At invitation of Dr. Davis, of Hartford, the Society met socially at his elegant house at the edge of the city, where they were entertained right royally.

As a whole the meeting was quite a success, as it is said to be usually when it meets at Hartford. The only serious drawback was the crowding out of several papers of interest.

After adjournment the members gathered around the "festive board" at the United States Hotel, where some good speeches were made by delegates from sister societies and invited guests.

# Medical and Surgical Journal.

THURSDAY, JUNE 18, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly by CUPPLES, UPHAM & Co., Boston. Price, 15 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM AND COMPANY,

283 WASHINGTON STREET, BOSTON, MASS.

## DR. H. P. WALCOTT AND THE MASSACHUSETTS BOARD OF HEALTH, LUNACY, AND CHARITY.

WE believe that Governor Robinson has made a mistake in not reappointing Dr. Walcott to this State's Board of Health, Lunacy, and Charity, from the point of view of political expediency as well as of the public welfare. We are informed that the alleged cause of his failure to make an appointment so eminently fit is in the interest of "harmony" in a board where *personal* and *political* influences are so prominent that no harmony except the harmony of mediocrity or of subservency is possible.

So able and upright a public officer as Dr. Walcott must necessarily meet the most violent opposition in any body of men and women who would uphold as chief of a department a man of the character of the late superintendent of Out-door Poor, until the addition of three members appointed by Governor Butler made possible his summary retirement into private life.

At that time ex-Governor Talbot, then chairman of the board, used the party whip so vigorously in behalf of Mr. Wheelwright, Dr. Walcott was the only republican who voted against him. For this he has not been forgiven, and we believe this to be really at the bottom of his being turned out of office now. If Governor Robinson has any valid reason for removing Dr. Walcott from an office which he has honored, we challenge him to produce it. If he has given himself over to those members of the board who sustained Mr. Wheelwright, we wish him joy of his position.

It has not been to the credit of the Board of Health, Lunacy, and Charity that it has maintained so long and so obstinately a source of public scandal at the State House, thereby giving foundation for some of General Butler's worst accusations against the management of our public charities, and causing many people who knew something of the bad in our official life to suspect also what was good. If, however, we are correctly informed that the conception and creation of this ill-assorted, incongruous, unwieldy board, with the long name and the mixed functions, was a clever device of the

late head of the Out-door Poor Department for strengthening his own position, it is perhaps a waste of words to wonder that he should have been able to retain the office so long, and we content ourselves with offering our modest tribute to his "smartness," a quality which has not been unemployed at the State House by his political patrons.

This struggle over the Out-door Poor Department has been in reality a long one. Former members of the board retired in disgust, utterly hopeless of accomplishing what Dr. Walcott, by his fidelity and courage, combined with a more favorable opportunity, has brought about, and for which the State owes him a debt of gratitude. It is unfortunate that the chairman of the board has been able to make use of the case of one of its subordinates, a clerk in the Out-door Poor Department, trained under the superintendent, Mr. Wheelwright, in such a way as to confuse the public as to the real issue in this controversy. We understand the circumstances of the case to be as follows: An employee of the board, in the department of the board formerly controlled by Mr. Wheelwright, had been indicted for bastardy, in Lowell, by a woman of bad character. The case was investigated by a trusted officer of the board who believed, as Dr. Walcott and we believe, that the accusation was a groundless one.

We understand from Dr. Walcott's letter to the *Advertiser*, on the twelfth instant, that Chairman Donnelly suspended the man from office on his own authority, which he had no right to do under the by-laws of the board, and that he also, at the same time, acknowledged the possibility of innocence of the charge by suggesting that the salary of this clerk be paid during the time of his suspension, if found not guilty; that Dr. Walcott insisted upon a hearing by the board; that, at this hearing, a general state of founess, long suspected, was proved to have existed in an important department of the board, for which the former head of the department, Mr. Wheelwright, was responsible, and of which he was the head centre; that the chairman of the board wished to turn the employee out at once; that Dr. Walcott thought it fair to give him a chance to defend himself against a charge which he believed groundless and to which innocent officers of the board engaged in looking after bastard children might be exposed, and that he, instead of making one poor victim a scapegoat, wished to make this case a means of investigating that whole Department of Out-door Poor, and thus clean out a mass of filth from the State House, the extent of which—how much had been retained since the superintendent's virtual dismissal from the board—no one had any means of knowing.

That Dr. Walcott was right, we fully believe, and in that he accomplished a work which former conscientious members of the board, Mr. David L. Webster, Drs. Hosmer and Folsom, hoped, but were unable, to do, he is to be congratulated.

Considering the disgusting nature of the revelations made, the number of "good persons and timid politicians" who permitted such a burning disgrace to last for so many years, and especially considering the uncomfortable revelations which the late superintendent of Out-door Poor might make if driven into a corner, or put into the witness-box, we do not wonder that Mrs. Leonard and Mr. Donnelly, and Governor Robinson and the "grand old party," found themselves in a very bad fix, and that in attempting to cover up a shameful state of things instead of coming out with the truth they thought Dr. Walcott the kind of a man of whom they must rid themselves by fair means or foul, and as early as possible.

An unfortunate issue has been made in the whole affair by the *Globe's* warm defence of Dr. Walcott, thereby seeming to give the matter a political significance which it does not possess. Dr. Walcott, however, in this respect, has fared no worse than another former member of the board whom it served the *Globe's* purpose for the moment at one time to revile and at another time to praise.

The history of the old Massachusetts Board of Health and of its successor—this unfortunate Board of Health, Lunacy, and Charity—has for us and for our readers a deeper interest and a greater importance than any mere petty question of local politics, and party struggles, and personal jealousies, and individual political ambitions. We see reflected in it the birth, the struggles, and the future growth or decay of "preventive" medicine, of "State" medicine under a popular form of government. There is no more beneficent department of medical science, and at the same time no branch of State administration of more vital concern to the welfare of the people. Are active, honorable, independent, and competent men to be encouraged to labor in this field or not?

#### QUACKERY UNDER MARCUS AURELIUS.

THE reign of Marcus Aurelius belonged, according to Gibbon, to the most happy and prosperous period in the world's history. It was an age which gave a progressive impetus to the rising Christianity; the age of philosophers, than whom there was no greater than the Emperor himself; the age of Galen, and of the revival of rational medicine. Nevertheless no epoch was ever more rife in quackery. Renan says that it was the era of *fools*, and almost the only level-headed man among them was that "stray sage" Lucian.

Never was superstition more prevalent. The masses had greater faith in the power of amulets, charms, and incantations to remove disease than in the maxims of Hippocrates, and that "colossal idiot," Socrates, the Boeotian savage, had more followers than Galen. It is impossible to conceive

of such princely revenues accruing to any professional man for honest work as came into the possession of the most notorious charlatan of antiquity, Alexander of Abonotichus. Not only the poorer classes put implicit trust in such scoundrels, and supposed that for a few oboli they could purchase a charm which, pasted over the doors of their houses, would keep away the plague; but men first in rank and intelligence had faith in barbarian oracles, which they often followed to their destruction, and even the Emperor was not altogether free from the taint of superstition, as Lucian testifies.

The practice of medicine was largely mixed up with divination and soothsaying, and the advice of a dead Æsculapius was considered of more worth than that of a living Galen.

There were stringent laws on the statute-books against soothsaying, and against all impostors who aimed to make money by gulling an ignorant and credulous public,<sup>1</sup> but these laws were difficult of enforcement, and were virtually a dead letter.

The wise Emperor was one of the most tolerant of men. He lamented the degradation of the masses, but realized the powerlessness of repressive legislation materially to improve their condition; if the weeds of superstition flourish, it is because the mental soil is just suited to them, and if you root out one rank cluster, another quite as noxious will speedily spring up in its place. "He had vainly endeavored," says Renan, "to suppress the scenes of cruelty which were enacted at the amphitheatres, making them places of horror for every one with moral sensibility, but he could not succeed"; "these abominable representations were a part of the life of the people." The influences that transform society and purge it of error are of a moral and educational order rather than the product of any executive fiat. A singular episode in this eventful period was the career of the renowned imposter Alexander, of whom mention has been made. He began his rôle of fraud and deception with the determination to enrich himself by catering to the two most powerful passions of human nature—hope and fear. As the masses of mankind have always been impatient of the natural sources of knowledge, and eager for the hidden mysteries behind this material scene, he resolved to establish an oracle and become both a prophet and a healer. Lucian relates the means by which he beguiled the gaping multitude and acquired a reputation. In his travels he had obtained possession of an immense tame snake which he called *Algeon*; this he would wrap around his person and exhibit to visitors as the soul of Æsculapius incarnated. The tricks by which he imposed this belief on the people are detailed in Lucian's account. The real head of the monster was concealed from view, an artificial head resembling that of a man with forked protruding tongue being displayed instead;

<sup>1</sup> They were to be banished,—"ne a homine crederetur publici moris ad spem alienis rei corruptum curat."

by a species of clever ventriloquism the serpent was made to talk and utter oracles. The show was always made in dim light, and with a great deal of mystery, such as attends certain modern "séances." It was found convenient to deliver most of the oracles in writing. Those who desired to consult the "young Æsculapius" (as it was called) were required to send in their questions in *sealed tablets*; these to be returned to them unopened, the seals unbroken, but with the questions answered. It is a singular fact that we hear of certain "writing mediums" resorting to the same trick at the present day. Lucian explains very plausibly how he supposes the trick was done. He says that Alexander "heated a needle in the fire, and putting it under the wax, lifted up the seal, and read the book, then, by means of the needle, melting the wax again, easily fastened down both that which was under the thread and that which was around the seal." The next day the consultants had their tablets returned to them answered, and for this they paid a certain sum. Lucian has transmitted to us some of the medical prescriptions of this ophidian Æsculapius; they are sufficiently curious. To a patient complaining of a disorder in his bowels, he prescribed "swine's flesh in mallows," to be pounded together in a "consecrated vessel." To a person complaining of a pain in the side, he ordered an ointment of "bear's grease mixed with dew, which must be gathered during the full of the moon." Of such a character were the absurd prescriptions of those times. All medical writings of that age, with perhaps the single exception of Galen's works, are full of such trash as this, everything being the fruit of incomplete observation and unverified statement. Pliny's books are a collection of crudities, in which the medical part shows how encumbered was the *Materia Medica* of that uncritical age with abominations of all sorts.

Lucian and the Epicureans of that epoch seem to have been a sore trial to Alexander; Lucian put him to severe tests in which he caught him tripping every time. As a result the illwill of the imposter was obtained, and Lucian narrowly escaped a plot laid to take his life. He thereupon complained to the King of Pontus and Bithynia and asked that an edict for the arrest of the imposter should be granted. The king sympathized with Lucian, but dared not interfere and bring the scoundrel to punishment.

He was too popular at Rome: an ex-consul, Rutilianus, was his son-in-law, eminent senators believed in him, and an attempt to prosecute him would provoke a storm throughout the entire Roman Empire. Alexander lived to a ripe old age and died in all his glory; his statues about the year 178 A.D. were the object of public worship, and Nicomedia stamped its money with a representation of the serpent on one side and Alexander on the other.

The history of medicine involves many an instructive

chapter occupied with charlatanism of the grossest character. Theologians are fond of proving that all religious heresies have been continually repeating themselves; this seems also to have been largely true of medical heresies. There is much that is disheartening connected with medical practice under present social conditions; the demon of superstition has been *scotched*, not killed; the gullibility of mankind is still immense; charlatans prosper while men of modest merit toil on in honest poverty; nevertheless the psychological distance is a wide one between this age and the age when the charlatan of Abonotichus could deceive the clever heads of Rome; the advance is incalculable and the world will not go back.

#### A MASSACHUSETTS PHARMACY LAW.

A PHARMACY bill has at last been passed by the Massachusetts Legislature, and having received the signature of the Governor it is now a law of the State. It has been passed through the influence of the State Pharmaceutical Association, which, although it has been organized only three years, already includes over half of all the apothecaries in business in the State. The bill very nearly met defeat, as in former years, through the misrepresentations of its opponents that it was being pushed in the interests of the Massachusetts College of Pharmacy, when that institution in reality sedulously held aloof from any action in regard to the matter in order to give no just grounds for any such assertion.

This time the bill was so drawn as to avoid any reasonable objections to such legislation. The Governor is to appoint a board of registration in pharmacy, consisting of five skilled pharmacists of at least ten years' practical experience, no two to be in business in the same town or city. Each year the term of one of the five will expire, and a new appointment to the board is to be made. The board will meet at least three times a year. All who have been engaged in the business for three years at the time of the organization of the board can upon application simply be registered on payment of fifty cents; all others, however, will have to pay five dollars and prove their qualifications by passing an examination. All the fees received by the board, its secretary will pay into the State treasury monthly. From these fees the State treasury will pay each member of the board five dollars for each day actually spent in these duties, and also traveling expenses—provided that the fees paid to the board are sufficient. The records of registrations and fees will be open to inspection at the office of the State Secretary.

The board will report annually to the Governor its acts and the condition of pharmacy in the State. All apothecaries doing business without registration are liable to a fine of fifty dollars, and it is the duty

of the board to have complaints made against all such to the district attorneys. This act does not apply to physicians dispensing their own medicines, to wholesale druggists not retailing, to patent medicines, or non-poisonous domestic remedies usually sold by grocers.

The effect of this statute will of course very largely depend upon the character of the men appointed upon the board and their manner of examination for applicants. Yet the mere fact that there is such a board, and that an examination has to be passed, will doubtless deter very many of those who are conscious of their want of proper qualifications from seeking to enter this calling so important to our success as physicians; for whatever skill we may have exercised in our choice of the therapeutic remedy, it will be of no avail if the drug has not been well selected and properly dispensed by the pharmacist, while the health of our patients and our own reputations will be the principal sufferers.

Up to this time a considerable proportion of those engaged in the business of apothecaries have been unqualified, and many of the leading States of our Union have been compelled to pass pharmacy laws, which in most cases have been more stringent than this one.

#### AN INSTRUCTORSHIP OF HYGIENE IN THE BOSTON PUBLIC SCHOOLS.

THE Boston School Committee has for a number of years been shying skittishly at the question of medical supervision of the city's public schools.

It was found that they could not provide for direct inspection without exceeding their powers, so the same end was sought by establishing the office of instructor in hygiene. The opponents of the measure have hitherto secured its defeat either by voting against the office or by voting against the candidate.

But a complete change of sentiment was disclosed at the last meeting of the School Committee. The opponents of medical inspection became its supporters, and some of its supporters opponents.

The office of instructor in hygiene was voted quite suddenly, so suddenly that it seems as if the candidate to fill the office were waiting at the door. A competent and proper person might render the city the highest service in this position. An incompetent or unsuitable appointment will bring the office and the subject into discredit.

#### MEDICAL NOTES.

Dr. J. H. Carmichael, of Springfield, a homeopathic physician, recently read before a Worcester County medical society, a paper on "Nervous Exhaustion Consequent upon Concussion of the Spine," which was published *in extenso* in the medical

journal of that persuasion. It was subsequently discovered to have been copied almost verbatim and without credit from Erichsen's monograph on "Concussion of the Spine." An explanation seemed to be in order, which is made by the writer, thus: "The *idea* of nervous exhaustion being dependent upon a shock to the spinal cord was wholly original with me." And he naively adds: "Had Erichsen not written on the subject, I should have done so." "This explanation," he trusts, "will be satisfactory."

— We are happy to notice that the *amende honorable* has been made by the Massachusetts Society for Prevention of Cruelty to Animals for the attack made by them on the work of Professors Nichols and Sedgwick in connection with the experiments made by those gentlemen upon the effects of water-gas on animal life. Would that equal reasonableness characterized similar societies universally in their attitude toward such investigations. They say through their official organ: "A recent complaint was to the effect that parties in a suburban city were wantonly suffocating with gas dogs, cats, rabbits, and pigeons. It was found that, under the direction of the State Board of Health, an eminent chemist with a physiological professor had been conducting a series of experiments to determine the comparative danger in the use of gas made from coal and that made from water. As the investigations had been concluded we were unable to personally observe and judge of their character. We are, however, more than assured that no wanton cruelty had been practised, and that only a minimum of suffering had resulted from the experiments; that in view of their vital importance (exclusively for the protection of human life), as represented by one of the learned gentlemen who conducted them, we were fully persuaded that the end justified the means, and there had been no wanton violation of either the laws of humanity or of the Commonwealth."

#### Correspondence.

AD UNCAS.

MARCH 20, 1885.

Mr Editor, — In writing prescriptions, one often finds it convenient to end off as follows: —

Aque, ad ℥ iv  
or aquæ, q. s., ad ℥ iv  
or aquæ, q. s., ut ft ℥ iv

Having had some doubt as to the classical correctness of these formulae, or at least of the first two, I addressed a letter the other day to Prof. George M. Dam, of Harvard College, who referred the matter to a pupil, Mr. Morris H. Morgan, and has sent me an interesting reply containing the result of Mr. Morgan's investigations and his own indorsement. Mr. Morgan finds each of the forms above given to be correct, and gives the following examples from classical writers to prove it.

In the work "*De Re Culinaria*," said to be written

by the noted epicure Apicius, is a receipt for mullet auge, part of which is as follows:—

"*Cuminum tritum quantum quinque digitis tallis, aperit ad demidium ejus.*"—Apicius ix. 13.

"*Aedem Junoni ad partem demidium delegit.*"—Livy 2, 3, 2.

"*Quasi ad talenta quindecim coegi.*"—Ter. 1, 1, 93.

"*Pecunia ingenuis humore egeat et ad periculis sufficit mnes.*"—Livy 4, 30.

"*Ad quod ei vires non suffecerunt.*"—Quinct. 12, 1, 12.

The examples of *at* with the subjunctive are of course numerous and need not be quoted.

The question is certainly more curious than important, but not without interest to those who like to write correctly.

Yours respectfully,

EDWARD H. WILLIAMS.

## POOR FOOD AT THE MASSACHUSETTS

### MEDICAL DINNER.

BROCKTON, MASS.

*Mr. Editor.*—If the Massachusetts Medical Society is unable to obtain a better dinner than has been its fortune this year, at its annual meeting, I would suggest for the next season that each member shall repair to the quarters of the Society with a picnic-basket, filled with food of home manufacture. Certainly they would be surer of neatness and variety, and perhaps style, than the exhibit of this year.

Truly yours,

H. F. BORDEN, M.D.

## REPORTED MORTALITY FOR THE WEEK ENDING JUNE 13, 1885.

Deaths reported 2,978; under five years of age 634; principal infectious diseases (smallpox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhœal diseases) 310, consumption 331, lung diseases 224, diphtheria and croup 86, diarrhœal diseases 67, scarlet fever 56, malarial fevers 27, typhoid fever 17, measles 22, cerebro-spinal meningitis 15, whooping-cough eight, erysipelas seven, purpuriferous fever seven. From malarial fevers, New York eight, New Orleans seven, St. Louis five, District of Columbia, New Haven, and Charleston two each, Philadelphia one. From typhoid fever, Philadelphia five, New York four, Baltimore three, Boston, St. Louis, Cincinnati, District of Columbia, and Charleston one each. From measles, New York 13, Philadelphia three, Boston, Cincinnati, District of Columbia, New Haven, and Lowell one each. From cerebro-spinal meningitis, New York and Philadelphia three each, St. Louis and District of Columbia two each, Cincinnati, Nashville, and Holyoke one each. From whooping-cough, New York and Philadelphia two each, District of Columbia, Nashville, Holyoke, and New Bedford one each.

Cases reported in Boston: measles 98, scarlet fever 36, diphtheria 22, and typhoid fever three.

In 68 cities and towns of Massachusetts, with an estimated

population of 1,055,571 (estimated population of the State 1,955,501), the total death-rate for the week was 16.51, against 15.43 and 18.19 for the two preceding weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,906,416, for the week ending May 23d the death-rate was 21.4. Deaths reported 3,594; infants under one year of age 825; acute diseases of the respiratory organs (London) 305, measles 182, whooping-cough 158, diarrhœa 42, scarlet fever 40, fever 37, smallpox (London 28, Manchester and Sheffield two each, Hull and Sunderland one each) 34. The death-rates ranged from 13.3 in Bolton to 34.5 in Blackburn; Birkhead 23.5; Birmingham 20.9; Bradford 17.3; Hull 19.9; Leeds 20.2; Leicester 18.0; Liverpool 24.2; London 19.3; Manchester 21.4; Sheffield 20.8. In Edinburgh 18.1; Glasgow 24.8; Dublin 31.2.

For the week ending May 23d in the Swiss towns there were 38 deaths from consumption, lung diseases 30, diarrhœal diseases 12, erysipelas four, typhoid fever three, whooping-cough two, smallpox one, purpuriferous fever one.

The death-rates were: at Geneva 15.2; Zurich 23.3; Basle 22.7; Berne 21.8.

The meteorological record for the week ending June 6th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending	Barom-eter.		Thermometer.		Relative Humidity.			Direction of Wind.		Velocity of Wind.		State of Weather. <sup>1</sup>			Rainfall.
	Daily Mean.	Daily Mean.	Maximum.	Minimum.	7.23 A. M.	3.23 P. M.	11.23 P. M.	7.23 A. M.	3 P. M.	11.23 P. M.	7.23 A. M.	3.23 P. M.	11.23 P. M.	Duration, Hrs. & Min.	Amount in Inches.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JUNE 6, 1885, TO JUNE 12, 1885.

FRYER, B. E., major and surgeon, U. S. Army. Ordinary leave of absence extended six months from July 1, 1885, on surgeon's certificate of disability. S. O. 129, A. G. O., June 6, 1885.

The order directing Major P. J. A. CLEARY, surgeon U. S. Army, to change station from Fort Union, N. M., to Fort Lyon, Col., is revoked. S. O. 81, Department of Missouri, June 8, 1885.

RICHARD, CHARLES, captain and assistant surgeon. Granted leave of absence for three days. S. O. 128, A. G. O., June 5, 1885.

MACAULEY, C. N. B., first lieutenant and assistant surgeon. Relieved from duty at Fort Sisseton, D. T., and ordered for duty at Fort A. Lincoln, D. T. S. O. 61, Department of Dakota, June 5, 1885.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE WEEK ENDED JUNE 6, 1885.

WYMAN, WALTER, surgeon. To inspect unserviceable property at Baltimore, Md. June 6, 1885.

CUTLER, H. R., passed assistant surgeon. To inspect unserviceable property at San Francisco, Cal. June 6, 1885.

BATTLE, K. P., assistant surgeon. To inspect unserviceable property at New Orleans, La. June 6, 1885.

#### SOCIETY NOTICES.

AMERICAN LARYNGOLOGICAL ASSOCIATION.—The seventh annual congress of the American Laryngological Association will be held in Abstract Hall, Lafayette Avenue, Detroit, Mich., June 21, 25, and 26, 1885. The profession is cordially invited to attend the sessions of the congress.

June 21th. Morning session at 10 o'clock. Roll-call, reception of guests, etc. Address of Welcome, by Dr. David Inglis, President of the Detroit Medical and Library Association. President's Address. Papers: (1) E. L. Shirley, M.D., Detroit, "On the use of Galvanism in Pharyngeal Affections." (2) F. H. Hooper, M.D., Boston, "The Respiratory Function of the Human Larynx." From experimental studies made in the Physiological Laboratory of Harvard University. Appointment of Nominating and Auditing Committees. Election of Fellows. Adjournment at 4 P.M.

Afternoon session at 3 o'clock. (3) H. A. Johnson, M.D., Chicago, "On some of the Motor Derangements of the Larynx, with cases." (4) William C. Glasgow, M.D., St. Louis, "On certain Vaso-motor Disturbances of the Nasal Membrane." (5) John S. Mackenzie, M.D., Baltimore, "Reflections on the Etiology of the simple Inflammatory Affections of the upper Air-passages." (6) D. B. Delavan, M.D., New York, "Erythema of the Pharynx and Larynx." Evening: Reception by the President to the Fellows of the Association.

June 25th. Morning session at 10 o'clock, promptly. Attendance meeting open to Fellows of the Association only. 1. Re-

port of the Secretary. II. Report of the Treasurer and Auditing Committee. III. Report of the Librarian. IV. Report of Committee on Nominations for 1885-86. V. Miscellaneous Business. At 11 o'clock the doors will be opened and the reading of papers commenced: (7) Frank L. Ives, M.D., New York, "Subcutaneous Laryngeal Hemorrhage, complicated by Cyst." (8) Harrison Allen, M.D., Philadelphia, "The Galvano-cantury in Laryngological Practice," with exhibition of a new cantury-saw. (9) A. H. Smith, M.D., New York, "The Principles involved in the Construction of Spray-tubes." Presentation of Instruments, etc. Adjournment at 1 o'clock.

Afternoon session at 3 o'clock. (10) E. Fletcher Ingals, M.D., Chicago, "Leucoplacia Buccalis." (11) R. P. Lincoln, M.D., New York, "A Case of Melano-sarcoma of the Nose, cured by Galvano-cauterization." (12) J. O. Roe, M.D., Rochester, "Anatomia of the Nose." (13) J. W. Robertson, M.D., Detroit, "Deformity of the Nose as a factor in Nasal Catarrh." (14) C. C. Rice, M.D., New York, "Inflammatory Adhesions of the Soft Palate to the Wall of the Pharynx." Evening: Annual Dinner of the Association at the Russell House, at 7 o'clock.

June 26th. Morning session at 10 o'clock. (15) Beverley Robertson, M.D., New York, "Alimentation in Laryngeal Pathosis." (16) F. H. Bosworth, M.D., "An additional Note on the Theoretical Action of Cocaine." (17) S. Solis-Cohen, M.D., Philadelphia, "Personal experience with some recent additions to the Materia Medica of Laryngology." (18) G. W. Major, M.D., Montreal, "A Case of Membranous Nasal Catarrh." (19) William F. Duncan, M.D., New York, "On the Influence of Diathesis on Mucous Membrane." (20) J. Solis-Cohen, M.D., Philadelphia, "On the Efficacy of Mild Measures in the Treatment of so-called Nasal- and Naso-pharyngeal Catarrh." Ballot for officers, 1885-86, and their induction into office. Adjournment at 1 o'clock.

Afternoon, at 2 o'clock. Boat ride on the river, by invitation of the Detroit Medical and Library Association.

#### BOOKS AND PAMPHLETS RECEIVED.

A Case of Extensive Recurrent Sarcomatous Disease. Read before the Philadelphia County Medical Society, May 20, 1885. By John S. Miller, M.D., Assistant in Surgical Clinic, Jefferson Medical College Hospital. (Reprint.)

Medical Legislation. The Annual Address before the American Association of Medical Editors. By Henry O. Marcy, A.M., M.D., Boston. (Reprint from Journal of American Medical Association, May 2, 1885.)

Medical Thoughts of Shakespeare. By R. Rush Field, M.D., member of the Shakespeare Society of New York. Easton, Pa.: Andrews & Clifton. 1885.

A Comparative Review of Quarantine and Maritime Sanitation. A Letter excerpted from the New Orleans Medical and Surgical Journal for June, 1885.

Report of the Board of Managers of the Pennsylvania Hospital to the Contributors at their Annual Meeting, held 5th Month 1th, 1885. Philadelphia.

A CASE OF TRAUMATIC LINEAR ATROPHY.<sup>1</sup>

BY VINCENT Y. BOWDITCH, M.D., OF BOSTON.

DURING the past year my attention was called to an affection of the skin, the symptoms of which were so marked and peculiar that I have thought it worth while to present the case to you this evening.

Mrs. A., a widow, aged sixty, with children, a person of decidedly sensitive and nervous temperament, has had for many years slight aortic disease, which in the last two years has shown somewhat more marked symptoms, together with a decided increase in bodily weight. Early in the past year she began to have an annoying paroxysmal cough, which, after repeated examinations of throat and lungs, with negative results, I came to the conclusion was of nervous origin, and, owing to her generally debilitated condition, I prescribed change of scene and air, and sent her to a relative's house in the country. On the twenty-sixth of February, a year ago, I was called to see her, and found the cough was still quite severe, at times causing vomiting and much dyspnoea. The patient complained also of an extreme sensitiveness confined to the lower abdomen. Upon examination nothing abnormal was to be seen, but, upon palpation, the walls of the abdomen, which was large and pendulous, were very sensitive, which symptom I regarded as rather hysterical than otherwise. I prescribed, however, a liniment containing aconite root and chloroform, with soap and opium, and did not see her until the following week, when she sent me word that several small puffy excrescences had appeared upon the abdomen, accompanied by a feeling of great heat and distension. Upon examination, the lower quarter of the abdomen down to the pubes and Poupart's ligament was very hyperæmic, and, ramifying in every direction upward, were curious, whitish, adenomatous-looking elevations from one eighth to one fourth of an inch in width, most marked near the pubes and median line, and gradually disappearing toward the line where the hyperæmia ceased; the whole having in arrangement the appearance of the branches of a tree, and giving to the finger the sensation of very soft, crumpled rice-paper. I ordered the liniment to be discontinued, and a lotion containing the acetate of lead was substituted. The following week the hyperæmia increased, and the elevations had increased in size, in some places having conflated so much as to make lumps as large as half of a pullet's egg. There was no marked tenderness, but a feeling of heat and puckering all the time, with a sense of distension of the parts, which caused much discomfort to the patient when sitting upright in a chair. The general symptoms were not materially changed.

Not being satisfied with the course of the trouble I called in consultation Dr. J. C. White, who considered it a very marked and rare case of either linear atrophy or keloid, and recommended leaving off all applications and using an abdominal supporter to relieve the tension of the skin. Owing to delay in obtaining the supporter it could not be

applied until some two weeks later, and as the hyperæmia and the elevations seemed to be slowly disappearing, I decided not to use the supporter, and see if the abdomen would not regain its natural appearance without aid of any sort. Two weeks later the hyperæmia and swelling had entirely disappeared, leaving only numerous cicatrices similar to those noticed on the thighs and abdomen of a woman who has borne children, or whose abdomen is large and pendulous.

In the *Journal of Cutaneous Medicine* (vol. i. p. 140) Sir. Erasmus Wilson speaks of "Striæ et Maculæ Atrophicæ Cutis, or false cicatrices of the skin." By these names he designates the whitish, slightly curved, puckered streaks so well known to us as seen on the abdominal walls and thighs of women who have borne children. He considers that these marks are due to rupture of the corium, with loss of the subcutaneous fat, of the papillary layer of the derma, of its vessels and nerves, leaving a smooth and unmodelled epidermis. From this loss of substance arises the name of striæ atrophicæ, or linear atrophy. He mentions, also, the existence of similar false cicatrices in the skin which have arisen under different conditions from those of pregnancy, and divides them, according to the nature of their origin, into three classes of linear atrophy, namely: (1) neurotic, (2) traumatic, and (3) idiopathic.

Under the first head come the lines sometimes noticed over the course of cutaneous nerves which have been paralyzed. For instance, in cases of paralysis of the supra-orbital, the course of the nerve can be traced by the whitish line which marks the position of the nerve, and which, some time later, loses its sensibility and becomes atrophied, resembling the scar of a sword-cut, the line in this case being more firm and condensed than in the other forms.

Under the second head, namely, the traumatic form, Wilson considers all those cases which arise from overdistension of the skin from causes acting from within, and mentions the conditions of pregnancy, of dropsy, and obesity. He likens this condition to that of a rubber bag which is overdistended with gas; it first yields, and then gives way at the weaker places. He concludes: "In the corium this violence is accompanied with hyperæmia and followed by exhausted nutritive power and atrophy."

The third, or idiopathic, form he considers appears without apparent cause, although the nutrition of the skin is evidently affected by an unhealthy general condition. Unlike the traumatic form, moreover, it appears in parts of the body not subjected to distension of any sort.

This case I class under the second head, namely, linear atrophy of traumatic origin. We have the history of long-continued paroxysmal cough, causing frequent and violent distension of the abdominal walls, which, owing to the debilitated condition of the patient, yield in the manner mentioned above, and after two or three weeks of acute hyperæmia and swelling a gradual diminution of the symptoms occurs, until no vestige of the trouble is left except the small cicatrices of the ruptured corium.

In this case the symptoms were all unusually well marked, and to one whose attention had never been

<sup>1</sup> Read before the Section for Clinical Medicine, Pathology, and Hygiene of the Suffolk District Medical Society, March 11, 1885.

called before to the affection the appearance was decidedly puzzling, not to say alarming.

*Diagnosis.*—The only other disease with which linear atrophy could be confounded is the so-called "keloid," and several authorities speak of the marked similarity between the two affections, and the frequent difficulty of distinguishing one from the other. Cases of the latter are divided by most authors into two classes, namely, the true and the false keloid, according to the idiopathic or traumatic origin of the affection.

True keloid is the name applied to an affection characterized by a collection of small red tubercles, usually found upon the sternum, sides of the body and back, which increase in size slowly until they coalesce, forming oval or cylindrical-shaped tumors, dry and puckered in appearance, with spur-like processes, somewhat tender upon pressure, and firmly rooted in the skin. This process of growth may go on for months or years with more or less discomfort to the patient from a sense of burning or itching, and the affection rarely disappears, although exceptional cases are reported in which entire disappearance of the tumors was noticed.

False keloid is a term used to designate the exaggerated cicatricial tissue noticed in places where a wound has previously existed, and differs from the true form in that it is usually smaller, longer, bifurcating, and follows the course of the original lesion. The difficulty oftentimes of drawing the line between true and false keloid is spoken by Kaposi in his article on "Keloid," *Lehrbuch der Kinderkrankheiten*, vol. ii.

The course of the disease, its sudden appearance and comparatively rapid disappearance, the absence of tenderness in the tumors themselves, are facts which enable us to decide against the presence of keloid in the present case. The slight elevations noticed resembled the tumors of that disease, but their rapid shrinking, leaving nothing but the ordinary atrophic lines, is another proof of the non-existence of keloid.

Treatment is of little avail in these cases, and the disease will, as a general thing, run its course uninfluenced by medication. Attention to the general health and an attempt to remove the exciting causes are chiefly indicated, as in this case, for instance, where an attempt was made to relieve the pressure on the walls of the abdomen by means of a supporter, medicines to relieve the paroxysmal cough were given. Sedative applications are of little or no use in checking the course of the affection.

In conclusion, the question might naturally arise, Could the affection described have arisen from the application of the liniment containing aconite-root and chloroform, with soap and opium? Such a supposition can hardly be sustained: *first*, from the fact that no case has ever been recorded of similar trouble arising from the use of this very common remedy; *second*, because attention had been called to the extreme sensitiveness of the lower part of the abdomen before any external applications were made; and *third*, because similar affections, in which the general symptoms were like those mentioned in this case, have been recorded by various authorities.

### MULTIPLE SARCOMA OF THE SKIN: TREATMENT BY HYPODERMIC INJECTIONS OF FOWLER'S SOLUTION: RECOVERY.<sup>1</sup>

BY FREDERICK C. SHATTUCK, M.D.,

*Instructor in Theory and Practice in the Harvard Medical School; Physician to Out-Patients at the Massachusetts General Hospital.*

JULY 26, 1883. K. B., thirty-one years old, was admitted into the Massachusetts General Hospital. Her health had usually been good, and she had worked at dressmaking up to the time of admission. Seven months before that date she began to suffer from pain along the lower jaw, and soon after noticed swelling behind the angles of that bone. About two months later nodules appeared in the skin over her right shoulder, then on her right arm, next on the left, next on the abdominal wall. She thinks that the appearance of the nodules was preceded by local tenderness and followed by discoloration. About three weeks ago she noticed that her face was fuller than normal, and she began to suffer from pain in the cardiac region. She was somewhat short of breath on exertion, and reported that she had lost decidedly in strength, though not in flesh. The bodily functions were in fairly good order. The pulse was 120, regular, rather weak.

On examination, it was noted that the patient was pale, with some edema of the eyelids and face, preponderating on the right side. Scattered throughout the skin of the upper extremities and the body as far as the umbilicus were hundreds of nodules, mostly about the size of a pea. Over the inner aspect of the arms the nodules were discrete, not raised above the surface, slightly tender on pressure; the skin could be wrinkled over them, and was not discolored. On the outer hand, over the shoulders, outer aspect of the arms, breasts, upper abdomen, and back — though in the latter situation to a less degree — the nodules were so thickly sown as to form large masses or plates, very hard and but very slightly tender; the skin covering these could not be pinched up or wrinkled, and was markedly erythematous, with slight scaly desquamation of the epidermis. In the legs a very few nodules could be felt, and there was no erythema. The glands at the angles of the jaw were enlarged, but those of the axilla and groin were apparently normal. Thorough examination failed to reveal any material modification of the great viscera. I made the diagnosis of multiple sarcoma of the skin, and soon after Drs. White, Wigglesworth, and Tilden were kind enough to accede to my request to see the patient, concurring in the diagnosis.

General tonic treatment was prescribed at first, but Köbner's brilliant success in a similar case with the subcutaneous use of Fowler's solution induced me to adopt his plan toward the end of August.

<sup>1</sup> Read before the Section for Clinical Medicine, Pathology, and Hygiene of the Suffolk District Medical Society, March 11, 1885.

An injection of four minims, diluted with an equal quantity of water, was given once daily, deep in the thigh. September 15th Dr. Tarbell resumed charge of the wards, and soon after increased the injection to six minims. The general health of the patient improved, a few fresh nodules appeared, but the old ones disappeared in much larger numbers, and November 3d she was discharged from the hospital, in order that she might work a portion of her time. She came daily to the hospital, however, for her injection until she was furnished with a syringe and taught its use, and treatment was persisted in steadily till the middle of March, when I opened an abscess in the thigh, the only one which formed during the whole time. A few nodules still remained, but the masses which filled the skin over the breasts, abdomen, and outer side of the upper arm had entirely disappeared, and during the past year she has been under observation from time to time without any treatment whatever, and has worked steadily at her trade. I have seen her within a few days, and she remains perfectly well to all appearance.

Early in 1884 I showed her at a meeting of the Medical Improvement Society, but have purposely allowed a year to elapse before reporting the case, in order that there might be no doubt as to the result.

Cases of multiple sarcoma of the skin are rare, and the authorities on diseases of the skin have little to say on the subject. All agree that the prognosis is absolutely unfavorable, and the course generally a rapid one. Köbner's is the only case recorded up to date, so far as I am aware, in which recovery took place. I now regret that one of the tumors was not excised and examined microscopically, as was done by Köbner. The patient was extremely averse to the operation and preferred to wait, promising that she would make no objection if she got worse. To this delay I consented, having very little faith that treatment would prove of any avail. Still, even without the evidence of the microscope, I think there can be no doubt as to the diagnosis. The experts were unanimous and I had previously seen two other cases very similar, except that they ended fatally. Was the cure really attributable to arsenic? If so, would the drug have acted as well administered in the usual way by the stomach? These are questions which can only be answered by extended experience. It is interesting to state that ten days after the arsenic was stopped the urine was examined for its presence by Professor Wood with a negative result.

### INCREASED FREQUENCY OF SCABIES.

BY F. B. GREENOUGH, M.D.,

*Physician to the Boston Dispensary, Department for Diseases of the Skin.*

Nor only my own experience, but also that of my colleagues who see cutaneous disease in our public medical services, show that the frequency of scabies has of late increased in the most extraordinary manner. During, and just after, the war, scabies was by no means uncommon, but the cases gradually diminished in frequency, and in the decade 1870 to 1880 a case of itch was exceptional enough to be of especial interest, even in special practice.

The following figures, taken from my Dispensary casebooks will speak for themselves: In the first 5,000 cases of skin disease which I collated, there were 55 cases of scabies, making an exact percentage of 1.1. These 5,000 cases were observed in a period of time extending from July 1, 1873, to November 25, 1876. My next series extended from November 26, 1876, to June 30, 1878, and numbered 2,494. In this number only 8 cases of scabies were seen, or about .3 of 1 per cent. From this date my cases are numbered and classified yearly, the year beginning on July 1st and ending on June 30th. For the year ending June 30, 1879, the percentage of scabies was about .4; for 1880 a little over 1; 1881, .8; 1882, 2; 1883, 5, and 1884, 8.5. As the year ending June 30, 1885, is not yet completed, I have not my condensed report to refer to, but I find that from last January 1st, to June 15th, 85 cases of scabies are recorded in a total of 477 cases of skin disease seen, making nearly a percentage of 18! I have not been able to explain this great spread of the disease in any other way than by referring it to the natural contagion by contact in crowded centres, and to the fact also that it had become so comparatively rare as not to be generally recognized. It certainly is not due (primarily at least) to importation, as a very small number of the patients were recent arrivals from abroad. The cases, for the most part, have been children and mechanics. The former undoubtedly get infected at school, and the latter in their workshops or lodgings, as it is quite common for our young mechanics to share a room together. A certain number of cases were, as a matter of course, seen in tramps, the outcasts who sleep in the station-houses, but I have been astonished to see how many of them were comparatively clean, hard-working young men. Whatever the source of the trouble may be, it is certain that if it continue to spread in anything like its present ratio, it will be a serious public misfortune. At this time of the year an exodus from the city takes place, and should scabies get well distributed in our manufacturing centres, agricultural districts, and lumbering camps of our neighboring States, it will not be easily kept in check.

The contact between the different classes, moreover, is such that it will not be confined to the lower strata of society. In fact, I have already this year seen some half-dozen cases, in my private practice, in individuals whom one would suppose exempt from such contagion. These facts have induced me to call the attention of the profession to this matter, more especially, as scabies from its nature, unless recognized and properly treated, is sure to increase in severity and attack those with whom the subject is brought in contact.

It would be a question if the disease continue to increase in the city, whether it would not be of sufficient importance for the Board of Health, or city physician to instruct the public-school teachers, police station captains, visitors for the various benevolent and religious societies, to see that all suspicious cases are examined and treated if found to be infected.

The diagnosis of scabies is by no means always easy, and I have been especially struck with the

comparatively few cases in which the typical "burrow" is to be found. But where the disease is prevalent, the existence of vesicles or pustules between the fingers, about the wrists, especially about the end of the ulna, signs of scratching on the forearm, with an eczematous eruption at the elbows, and a history of increased itching after getting to bed, the diagnosis of scabies may be made with safety. In such cases the nightly use of a very inexpensive ointment, made of one part of carbonate of potash, two of washed sulphur, and three of lard, washed off in the morning with soap and water, will certainly benefit the patient, and diminish his infecting power, if it does not cure him. This sulphur ointment should not, however, be applied to places where there is much irritation of the skin.

Even such simple routine treatment as this, used in schools, factories, or other collections of individuals, where scabies was spreading, would have a decided effect. It is, however, with no idea of writing on the diagnosis and treatment of scabies that I pen this brief article, but simply to make public certain statistical facts, which seem to me of importance with reference to the general welfare.

## REPORT ON DENTISTRY.

BY WILLIAM HERBERT ROLINS.

### (a) SIZE OF THE TEETH AS A CHARACTER OF RACE.

W. H. Flower divides mankind into three classes, according to the relation between the size of the skull and that of the teeth. He finds these divisions correspond with the three principal modifications of the human species. The white races belong to his microdont division, the yellow to his mesodont, the black to his megadont. To obtain his dental index, he takes two measurements. The first, called the dental length, is the length of the crowns of the five upper teeth of the molar series. The second is the cranio frontal, found by measuring the distance between the naso-frontal suture and the anterior edge of the foramen magnum. The dental index is found by the following formula:

$$\frac{\text{Dental length}}{\text{BN}} = \text{dental index};$$

D representing the dental length; BN the cranio frontal. When the dental index is below 12, the skull belongs to the microdont class; if between 12 and 14, to mesodont; if above 14, to the megadont.

### A PARTLY LOST MOVEMENT OF THE JAW.

Thomas S. Solinsky<sup>1</sup> has examined the teeth of many skulls taken from the mounds in Missouri, and finds that the incisor teeth, instead of presenting cutting edges, are worn down until the tops are circular in outline. This, he thinks, is due to a pronounced forward and lateral swing of the jaw in chewing, during which the incisors, instead of overlapping, cross each other. He suggests that the disuse of this swinging movement of the jaw has tended to change the facial outline, increasing the length of the visage in proportion to its width.

### DENSITY OF THE TEETH.

V. Gallipe<sup>2</sup> states that the density of teeth varies from year to year in the same individual according to the general condition of the body. There is also from childhood to old age a gradual increase in density. The teeth of women are less dense than those of men. On the right side of the jaw they are more dense than on the left. He found, when the mean density of all the teeth was 2.0181, the density of those on the right side was 2.110, while on the left side it was only 2.09.

### TEETH OF FUEGIANS.

V. Gallipe<sup>3</sup> mentions the following interesting points: The wisdom teeth erupt at the age of twelve years. The temporary canines are frequently retained, the permanent ones coming outside the arch. The density of the teeth is greater than in Europeans. They are a right-handed people, and the teeth on the right sides of their jaws are more dense than those on the left. Both upper and lower jaws form *semicircular* curves. The arch of the palate is very low. The crowns of the molars diminish in size from the first to the last.

The last observation, Gallipe thinks, negatives Darwin's view that in the higher races the wisdom teeth were becoming smaller. Darwin also thought the Fuegians among the lowest types, an opinion which Gallipe does not share.

This early eruption of the wisdom teeth and the rapid diminution in size of the crowns of the molars, from the first molar to the wisdom tooth, is a very peculiar condition for the teeth in savages.

### DENTAL CONDITION IN CONGENITAL ALVEOLAR FISSURES.

Oakley Coles<sup>4</sup> finds as the result of an examination of a series of cases that none of them showed a fissure of the alveolus occurring between a true lateral incisor and a canine. In half of the cases the central incisor is wanting on the side where the fissure occurs. In one third of the cases a precanine is present on the same side as the fissure. In none of the cases was there an increase in the number of teeth in the precanine region.

### RELATION OF ALVEOLAR CLEFTS TO THE INCISOR TEETH AND INTERMAXILLARY BONES.

W. Turner<sup>5</sup> agrees with Albrecht, who thinks there are four intermaxillary bones instead of two, as taught by Goethe. In the majority of cases of alveolar cleft palates, the fissure is between the edognathion and mesognathion of Albrecht. The position of this cleft is an interesting point, as it throws light upon the question whether the lateral incisor in man is really a lateral incisor (1<sup>2</sup>) or the third incisor (1<sup>3</sup>) of the normal dentition of placental mammalia.

It has been assumed that all teeth in front of the canines were incisor teeth, and that these teeth were all in the intermaxillary bones. In many cases of cleft palate an incisor tooth is situated outside (to the canine side) of the cleft. Obviously,

<sup>1</sup> Brit. Jour. Dent. Science, p. 388, 1884.

<sup>2</sup> Brit. Jour. Dent. Science, p. 628, 1884.

<sup>3</sup> Brit. Jour. Dent. Science, p. 312, 1885.

<sup>4</sup> Jour. of Brit. Dent. Association, 1885.

<sup>5</sup> Dental Practitioner, p. 217, 1884.

therefore, if this tooth is in an intermaxillary bone, the cleft, which is toward the medial line from the tooth, must be a cleft in an intermaxillary bone itself, if we accept the old idea of one intermaxillary bone for each side; while if Albrecht's view is the true one, this cleft represents the suture between the two intermaxillary bones of that side.

In many of these cases of alveolar clefts there is but one tooth on the medial side of the cleft, and this tooth has the characteristics of a central incisor (1<sup>4</sup>). It would seem, therefore, as if the view of Andrew Wilson (soon to be referred to) were the correct one. Otherwise the central incisor (1<sup>1</sup>) and the tooth to the outer side of the cleft (1<sup>3</sup>) should both be between the cleft and the medial line.

#### WHICH IS THE MISSING INCISOR IN MAN?

It has always been supposed that the missing incisors were the ones nearest the canines. Andrew Wilson<sup>6</sup> gives reasons for thinking that the suppressed incisor is not 1<sup>3</sup>, the one nearest the canine, but 1<sup>2</sup>; or, in other words, that the so-called lateral incisor in man is not a lateral incisor but a pre-canine, or 1<sup>3</sup>. He says where there are supernumerary incisors they erupt either between the central and lateral incisors or in the space immediately behind them. Cases in which three incisors are present on one or both sides in man are not very rare, and the middle one follows the lateral type. In a number of cases of alveolar clefts, where an extra incisor was present, it was invariably in the portion of the alveolus to the medial side of the cleft along with the central incisor.

#### MEASUREMENT OF THE TEETH IN THE INSANE.

W. H. Rhodes<sup>7</sup> took the interbicuspid measurements of forty of the inmates of the Cambridge Asylum, and found the average to be 31.78 mm., while in a like number of hospital patients it was 33.3 mm. No measurements were taken of the lower jaws, as these were found to show no signs of contraction.

#### (b) DEATH FROM GERMS IN HUMAN SALIVA.

W. D. Miller<sup>8</sup> examined a patient whose tonsils were concealed by a thick yellow coating, which was found to consist of masses of fungi, some of which were surrounded by a delicate, gelatinous sheath. A little of the saliva was brought in contact with sterilized calf-broth, and allowed to stand at a temperature of thirty-six degrees for five hours. One cc. of this solution was injected into the lung of a full-grown rabbit. Death occurred in thirty hours. The blood was crowded with cocci and diplococci, surrounded with gelatinous sheaths.

#### PROLIFERATION OF EPITHELIUM IN THE SAC OF AN ALVEOLAR ABSCESS.

Sections through the sac showed a lining of epithelium from two to eight cells thick, which sent a series of sprouts into the tissue, forming a network of epithelium, the meshes of which were filled with connective tissue infiltrated with pus cells.

#### A CYST IN A TOOTH.

G. R. Thomas<sup>9</sup> figures a longitudinal section of a bicuspid in which the pulp-chamber is separated into two cavities with no opening in the intervening plate of dentine. The upper closed cavity was filled with the remains of decomposed tissue. He thinks that the plate of dentine was thrown out by the pulp to protect itself from its own suppurating coronal portion.

#### AFFECTIONS OF THE GUMS AS CAUSES OF OTHER DISEASES.

Dr. Kaczorowski<sup>10</sup> has noticed cases in which chronic gingivitis produced hallucinations, melancholia, and insanity. Extraction of the decayed teeth and treatment of the gums was followed by recovery in all the cases. He thinks that septic products are often taken into the system from chronic conditions of the teeth and gums.

#### (c) TREATMENT OF ROUGH ENAMEL.

Dr. Francis grinds away the enamel entirely, if necessary, to produce a smooth surface, and considers that the polished surface so produced is less likely to decay than the original one.

#### UNION OF FRACTURED TEETH.

Dr. Wingate<sup>11</sup> practises in Carbondale, where there is a large class of miners, among whom accidents are common. He reports eight cases of united fractures in teeth. As these teeth were all extracted for pain which was caused by their distorted shape, it is probable that united fractures in teeth are much more common than has been supposed, for these teeth represented the failures only; the successful cases, not giving trouble, were never recognized.

#### NEW METHOD OF USING RUBBER WEDGES.

Instead of immediate and severe pressure from a thick rubber wedge, Dr. Genese uses a series of wedges beginning with one which is thin.

#### TIN AND GOLD AS A FILLING.

This method is called Dr. Abbot's, but the inventor is unknown. It consists of folding a sheet of gold and one of tin together and doubling them into pellets, which are wedged into the cavity. According to a recent writer,<sup>12</sup> this method has advantages.

Only a few minutes are needed to make a large filling. The material is so soft, it adapts itself readily to the walls of the cavity. The filling should be put in without any attempt to keep the cavity dry, as the moisture produces a molecular change resulting in an expansion of the filling, thus making it watertight after a few days.

#### GOLD-FILLING BY BURNISHING.

To Dr. Shumway, of Plymouth, belongs the credit of discovering that cohesive fillings could be made by burnishing thin layers of gold together. Herbst, a German, has recently rediscovered Dr.

<sup>6</sup> Jour. Brit. Dent. Association, p. 241, 1885.

<sup>7</sup> Jour. Brit. Dent. Association, p. 413, 1884.

<sup>8</sup> Independent Pract., p. 19, 1885.

<sup>9</sup> Dental Register, p. 12, 1885.

<sup>10</sup> Southern Dental Journal, p. 524, 1885.

<sup>11</sup> Independent Pract., p. 33, 1885.

<sup>12</sup> Miller, in Jour. Brit. Dent. Association.

Shumway's method, and all over the world burnished fillings are attracting great attention. The only new point in Herbst's rediscovery is the use of revolving burnishers. Shumway used hand instruments, a slower but far more delicate plan. The method should be named for Shumway, not for Herbst.

#### METAL CROWNS FOR MOLARS.

These, although so recently introduced, are rapidly supplanting the old laborious method of restoring with cohesive gold. They save the patient a large amount of nervous exhaustion necessarily attendant to the old method.

#### (d) CANNABIS INDICA IN EXTRACTION.

A. Aaronson<sup>13</sup> finds the tincture, when diluted to one-fourth strength, a perfect obtunder when applied to the gums before extraction.

#### COCAINE.

The most extravagant claims have been made for this alkaloid as an obtunder of sensitive dentine. It has no marked value for this purpose as a local application. When injected into the tissue near the inferior dental nerve, sensibility in the teeth supplied is diminished, but already several cases of injury to the nerve are reported. Besides, that way of applying it is about as severe as having an ordinary tooth filled without any obtunder. Its chief use about the mouth seems to be as an application to the gums; before adjusting the rubber dam, where the cavities are so deep that the rubber must be carried under the gum; before trephining in setting banded pivot teeth; and other similar operations.

#### GRANULATED BONE FOR THE TEETH.

A writer in the *Dental Practitioner* selects fresh bones, dries them, and grinds to a fine flour. These he prescribes to his patients in "soups, gravies, bread," etc., in the proportion of one to three "spoonfuls" to each pint of soup, gravy, or flour.

#### SULPHIDE OF CALCIUM IN ALVEOLAR ABSCESS.

Dr. Geo. B. Snow<sup>14</sup> recommends doses of one tenth of a grain of sulphide of calcium three times a day. It diminishes the pain and promotes rapid suppuration and healing.

#### NITROUS OXIDE AND OXYGEN.

Dr. E. P. Howland<sup>15</sup> mentions the advantages of Bert's mixture. Insensibility is complete in a few seconds; there is no danger of asphyxia; recovery of consciousness is rapid; there is no nausea.

#### BROMIDE OF POTASH IN TAKING IMPRESSIONS.

Dr. E. M. Sanger<sup>16</sup> gives thirty grains of this salt half an hour before the impression is to be taken. It prevents the spasmodic contraction of the muscles, which, in many persons, renders the operation impossible.

#### (e) ARTIFICIAL TEETH.

We have always supposed artificial teeth to be of modern origin, but Dr. Van Martin<sup>17</sup> has recently

figured and described two cases of carved ivory teeth, held in position by gold bands fastened to the natural teeth, which he found in the museum in Corneto-Tarquinius. He considers that there can be no doubt of the antiquity of these specimens of bridge-work which were taken from Etruscan tombs opened under the direction of authorities of the town of Corneto.

#### ADAPTING ARTIFICIAL PLATES.

Dr. C. H. Land<sup>18</sup> does not believe that plates are held in contact with the roof of the mouth by atmospheric pressure, but by capillary force. This he estimates to be equal to two pounds to the square inch.

#### CONTINUOUS GUM FACINGS.

These were spoken of in a recent report as a valuable modification of artificial plates. Dr. Haskell claims that Mr. Verrier is not the originator of the method, which is thirty years old; and worthless, because the case cannot be repaired without just as much labor as in making a new one.

#### GAS AS A FUEL FOR THE DENTAL LABORATORY.

It is surprising how difficult a matter it is to change the traditional customs in the laboratory. In the operating-room a new invention is considered better than the best old one, so progress here is rapid; but improved laboratory apparatus is rarely purchased.

Gas which in my laboratory is found capable of entirely taking the place of coal, coke, and charcoal gains few converts. With proper gas furnaces a dentist can himself do all that portion of dental ceramics needing artistic skill, while with coal and other solid fuels this delicate work must be done by a laboratory man, if done at all, on account of the labor and time needed.

## Reports of Societies.

### MASSACHUSETTS MEDICAL SOCIETY.

#### COUNCILORS' MEETING.

The annual meeting of the Council was held at the Medical Library, Boston, on the evening of Tuesday, June 9, 1885. One hundred and twenty-five Councilors were present. The meeting was called to order by PRESIDENT HOMANS at seven o'clock.

After the reading of the record of the previous meeting by the Secretary, and its acceptance, the roll of those composing the Council for the year 1885-86 was read. The Secretary announced the names of one hundred and three Fellows who had been admitted during the year, and of thirty-one who had died.

#### FINANCES.

The Treasurer's report showed the year's receipts—including a balance of \$1,562.86 from the previous year's accounts—to be \$10,022.75. The disbursements amounted to \$8,312.02, leaving a balance of \$1,710.73. The invested funds of the Society amount, as in the previous year, to \$32,420.17. The Society now bears upon its catalogue the names of 1,578 members.

<sup>13</sup> Brit. Jour. Dent. Science, p. 1636, 1884.

<sup>14</sup> Dental Advertiser, p. 37, 1884.

<sup>15</sup> Dental Advertiser, p. 77, 1884.

<sup>16</sup> Dent. Pract., p. 256, 1884.

<sup>17</sup> Ind. Pract., p. 1, 1885.

<sup>18</sup> Ind. Pract., p. 47, 1885.

In accordance with the recommendation of the Committee on Finances, reporting through Dr. Minot, it was voted that \$1,368.58, being eighty per cent. of the balance remaining in the treasury, be distributed among the District Societies.

#### REPORT OF COMMITTEE ON MEMBERSHIP.

DR. AYER, for the Committee on Membership and Resignations, reported a list of names of those desiring to become retired members, and of those wishing to resign. The Council voted in accordance with the recommendations of the committee.

#### THE REPORT OF THE COMMITTEE ON THE LIBRARY

was made by DR. Z. B. ADAMS, that the library consists mainly of reports of various medical societies. It was recommended that this property, and all similar publications hereafter received, be given to the Boston Medical Library, on condition that they be accessible to members of the Society. It was also recommended that the sum of fifty dollars be appropriated from the proceeds of the Society to aid in binding the pamphlets donated. The report of the committee was accepted and its recommendations adopted.

#### ELECTION OF OFFICERS.

The Committee on Nominations reported the following list of candidates for the offices of the Society for the ensuing year, and the same were elected by ballot: Dr. Charles D. Homans, Boston, President; Dr. George N. Munsell, Harwich, Vice-President; Dr. Frank W. Draper, Boston, Treasurer; Dr. Charles W. Swan, Boston, Corresponding Secretary; Dr. Francis W. Goss, Roxbury, Recording Secretary; Dr. Edwin H. Brigham, Boston, Librarian.

Dr. Richard M. Hodges, of Boston, was chosen Orator, and Dr. Edwin B. Harvey, of Westboro', Anniversary Chairman, for the next annual meeting.

#### THE NEXT MEETING.

It was voted that the next annual meeting be held in Boston on the second Wednesday of June, 1886.

#### APPOINTMENT OF COMMITTEES.

The President nominated, and the following were appointed to constitute, the standing committees:—

Of Arrangements.—Drs. H. C. Haven, C. H. Williams, J. W. Elliot, F. H. Hooper, J. B. Swift, H. C. Ernst.

On Publications.—Drs. G. C. Shattuck, R. M. Hodges, B. E. Cotting.

On Resignations.—Drs. J. Ayer, D. W. Cheever, J. Stedman.

On Finances.—Drs. F. Minot, B. S. Shaw, E. G. Cutler.

To procure Scientific Papers.—Drs. C. W. Swan, G. S. Stebbins, J. R. Chadwick, R. H. Fitz, H. P. Walcott.

On Ethics and Discipline.—Drs. G. J. Townsend, G. E. Francis, A. H. Johnson, C. Howe, F. C. Shattuck.

On Medical Diplomas.—Drs. W. L. Richardson, A. H. Cowdrey, E. J. Forster.

#### COLLEGE OF PHYSICIANS AND SURGEONS OF BOSTON.

The Committee on Medical Diplomas, to whom was recommended, February 6, 1884, the petition of the College of Physicians and Surgeons of Boston to be placed on the list of colleges whose diplomas are recognized by the Society, presented the following report:—

“The committee have carefully reconsidered the evidence then in their possession, and, during the eighteen months which have since passed, have accumulated an additional amount of information in reference to the manner in which the College has been conducted. In accordance with the instructions of the Council a second hearing was given, at which Dr. Dearing, the dean, and a committee consisting of Drs. Dudley, Wilson, and Gleason were present.

“After a careful consideration of the old and new evidence, the committee would report that, while they believe that some of the members of the Faculty have been, and are, acting in good faith, they as firmly believe that others of the Faculty have not so acted, and that, in some cases at least, the examinations have not been honestly conducted.

“They would therefore recommend that the degree of this College be not recognized by the Massachusetts Medical Society.

WILLIAM L. RICHARDSON,

A. H. COWDREY,

EDWARD J. FORSTER.

“BOSTON, June 8, 1885.”

After a prolonged and animated discussion the report of the committee was adopted.

#### CHANGES IN DISTRICT BOUNDARIES.

A petition from physicians in Stoughton that their town be transferred from the Norfolk to the Plymouth District was referred to the Presidents of the Suffolk, Norfolk, and Plymouth District Societies to report at the next meeting.

Voted, That the town of Hull be included in the limits of the Norfolk South District.

#### AMENDMENTS TO BY-LAWS.

The following amendments to By-laws were passed by the Council and referred to the Society for concurrence:—

By-law XX., lines 14 and 15, instead of the words “Thursday before the last Saturday of September and February,” read “third Thursday of September and December.”

By-law XX., lines 31–33, omit the words “provided, however, that the whole amount paid to any one Board shall not exceed the sum of sixty dollars for any single year.”

By-law XXIX., line 29, omit the words “a Committee, who shall report the same to.”

Adjournment was voted at 9.15 p.m., after which, by invitation, the Councilors proceeded to the residence of the President, Dr. C. D. Homans, where they were hospitably entertained.

—The bill for regulating the practice of medicine, reported by the Committee on Public Health to the Massachusetts Legislature, was defeated by an overwhelming majority.

## SUFFOLK DISTRICT MEDICAL SOCIETY.

SECTION FOR CLINICAL MEDICINE, PATHOLOGY, AND HYGIENE.

ALBERT N. BLODGETT, M.D., SECRETARY.

MARCH 11, 1885. Section called to order at eight o'clock. Dr. R. T. Edes in the chair.

The records of the last meeting were read and approved.

The first paper was by Dr. V. Y. BOWDITCH, entitled

## A CASE OF TRAUMATIC LINEAR ATROPHY.

The first speaker was Dr. WHITE, who stated that the process is not a true atrophy, but an overstretching of the skin by which its elastic fibres lose their contractility, and the bundles of fibrous tissue forming the skeleton of the corium and normally interwoven in the form of a network are pulled out straight and left in a permanently parallel direction. The papillae and the glandular structures are pulled farther apart and the former flattened down. The stretching of the corium might result in real fracture of its tissues. The process is at times accompanied by hyperemia, so that the streaks looked redder than the surrounding skin seen through the stretched and thinned epidermal layers. The cause is always a distension of the integument by some power acting beneath it, as pregnancy, a rapid accumulation of subcutaneous fat, ascites, and the like, and occurs principally over the abdomen, breasts, and thighs. It affects men as well as women, and may possibly be caused by rapid increase in size in young people. The present case presented some very uncommon features. The hyperemia and tenderness of the parts were as pronounced as in an active dermatitis. The elevation and firmness of the radiating ridges resembled keloid or hypertrophied scar formation, and must have been due to the presence of the products of inflammatory infiltration. The exciting cause was apparently the rapid accumulation of subcutaneous fat and the rending action of the spasmodic cough.

Dr. Edes asked the distinction between the scars of linear atrophy and those of pregnancy, and how the distinction can be recognized.

Dr. WHITE stated that at times hyperemia may accompany oedema.

Dr. H. I. BOWDITCH asked if the liniment applied could have caused or increased the hyperemia? to which the reader replied that in his opinion this could have had nothing to do with it.

Dr. LYMAN observed that we see similar cicatrices on the thighs of virgins and others who have never borne children.

Dr. WHITE admitted that this may occur, but it is generally in persons who have a large amount of fat, and results from simple distension. It is at times seen in the breasts of fleshy women. It is not a true atrophy, but results from a mechanical pulling out of the tissues from simple distension.

Dr. F. C. SHATTUCK read a paper upon

## A CASE OF MULTIPLE SARCOMA OF THE SKIN: TREATMENT BY SUBCUTANEOUS INJECTION OF FOWLER'S SOLUTION; WITH RECOVERY.

Dr. WHITE stated that two years had passed since the last report on Professor Köhner's case,

and, so far as he knew, the patient remained well. He saw no reason why the internal administration of arsenic should not work as favorably as the subcutaneous injection. He had at present a similar case of multiple sarcoma under treatment by Fowler's solution given by the mouth, but it was too early as yet to report results. Some forms of sarcomatous growths in the cutaneous tissues showed a marked tendency to spontaneous involution, that is, if we regard the so-called mykosis fungoides, or granuloma fungoides, or lymphadenoma, etc., as it is variously entitled, of this nature. In this affection, of which he had had recently two examples under observation, tumors the size of a hen's egg or larger will rapidly disappear, notwithstanding its malignant character. The pathology of this form of disease was not yet fully established, and, although several excellent microscopists had determined the presence of a sarcomatous structure in it, clinically it was distinct from the form presented in Dr. Shattuck's case. Pigmented sarcoma did not appear to undergo involution with or without treatment. In reply to Dr. Blodgett's comments he stated that he saw no reason why a sarcoma should not confine itself to the cutaneous tissues in some cases, just as carcinoma may be restricted for an indefinite number of years to the same structures without manifesting a tendency to invasion of other parts of the system or to general malignancy.

Dr. TILDEN showed the photographs of a case interesting in connection with Dr. Shattuck's paper. The case had been under Dr. Tilden's observation, having been sent to him by Dr. Vincent Bowditch and had been referred to by Dr. White as a variety of cutaneous sarcoma. The disease was more common than that which Dr. Shattuck had reported, there being recorded in medical literature from thirty-five to forty cases. In the majority of cases it occurred in the male sex, and most commonly in advanced middle life from forty to sixty years. The malady had no connection with syphilis and most of its victims had always been in good health. It began with fugitive, erythematous, and inflammatory lesions of the skin attended with great itching and desquamation. After this condition of the skin had lasted for some time, a year or more, there appeared the lesions which were characteristic of the disease, namely, cutaneous tumors appearing either on normal skin or in regions which were already affected by the inflammatory lesions already mentioned. These tumors increased in size until often the epidermis covering them was cast off, exposing to view the pathological tissue of which they were composed, from which exuded a thin fluid which dried and formed crusts. The most remarkable feature of these tumors, and one which had been mentioned by Dr. White, was that they often spontaneously and completely disappeared, apparently by reabsorption, at the same time that other lesions of a like nature were showing themselves in other parts of the body. The disease is of chronic course and fatal termination, and its clinical features are well understood, Bazin's excellent description leaving nothing to be desired in this connection. Its pathogenesis, however, has yet to be determined. It is regarded by Kaposi and also in this country as multiple sarcoma of the skin, while several German

authorities look upon it as a granular tumor of the skin, giving to the disease the name of granuloma fungoides. The French dermatologists regard the affection as belonging to the same category as Hodgkin's disease or pseudo-leukemia, where, without marked or permanent increase in number of the white corpuscles of the blood, there occurs general hyperplastic enlargement of the lymphatic glands and spleen, together with the formation of so-called cytogenic or lymphatic tissue in various parts of the body. Microscopic examination showed the tumors to be made up of a dense infiltration of the corium with round cells resembling lymph cells which, according to Ranvier, were contained in a fine, fibrillary network, presenting stellate connective tissue cells at the points of intersection of the fibrille, the presence of this network showing the new formation to be one of cytogenic tissue, and not sarcomatous in nature. Dr. Tilden had excised two of the tumors from the case in question, but had not yet had time to give them a thorough examination, and was of the opinion that if the presence of this lymphatic reticulum could be satisfactorily made out, that it would go far toward showing the cytogenic nature of these tumors. In determining the pathogenesis of any malady also, its clinical course should be taken into consideration as well as the minute anatomy of its pathological products, and the malady in question had many of the clinical features of pseudo-leukemia. In none of these cases had there been observed sufficient increase in number of the white corpuscles of the blood to constitute typical leucocythemia, and at the autopsies, as a rule, there had been found enlargement of the lymphatic glands, and often also of the spleen. The last case which had been reported was by Auspitz, in Vienna, last December, and in this case the tumors, upon investigation, have been found to contain large quantities of micrococci. Considering, however, the extremely favorable conditions in the shape of warmth and moisture furnished by these fungous excrescences deprived of epidermis, any microorganism found in them can hardly be regarded as anything but an accidental phenomenon.

Dr. LYMAN stated that he had a case under observation in which the features were similar to those described by Dr. Shattuck. The patient was seen some twelve or thirteen years ago. The skin was covered with small tumors. The patient died, and on autopsy similar growths were found in all the internal organs. Dr. Lyman asked if arsenic is usually given in doses so small as those reported.

Dr. WHITE replied that the amount given is never more than three minims at each injection.

Dr. SHATTUCK stated that the amount of the injection in the present case was increased to nine minims. There is an objection to large or bulky injections in that they sometimes produce severe pain at the seat of the injection.

Dr. BLOCHET considered it a matter of regret that a portion of one of the suspected growths was not removed and subjected to microscopical examination. The clinical history of the sarcomata is generally that of a most malignant form of disease, which tends to advance locally, and is often followed by degenerative changes in the growth, by which loss of substance and an ulcerating surface is

produced. One of the most uncontrollable and persistent features of sarcomatous disease is also found in the tendency which these growths possess of forming metastatic deposits in remote portions of the body and especially in the structure of the viscera. Each local deposit forming a new and independent local development of the original disease.

The specific treatment of sarcoma would seem to offer, *a priori*, less promise of success than would that of carcinoma, as the latter is confined originally to epithelial structures and is essentially an affection of an external surface of the body, while sarcoma is developed in the connective tissue, the *universal* tissue of the interior of the animal body.

Dr. BLOCHET suggested the possibility of the existence of a disease in the connective tissue which might resemble sarcoma in appearance, as the innocent verruca or common wart resembles a form of malignant carcinoma called papilloma, so closely that by the microscopical examination alone one might not be able to say which is malignant.

For this additional reason it would be of great advantage to secure a careful microscopical examination of the tissues in cases of this kind.

Dr. WHITE added that there is at present no known method of treatment which offers any promise of relief or cure in sarcoma. In ordinary cases the disease progresses in a way which shows the powerlessness of all medicinal measures for its restraint or cure.

Dr. WHITE suggested that in the absence of microscopical examination of the tissues it is possible that some other condition than sarcoma may exist.

The Secretary called the attention of the Society to a card which had been sent him announcing the presence in the city of a so-called "hermaphrodite," and stated that in company with three prominent members of the profession from Park Square he had visited the individual for the purpose of offering at the meeting of the Section a favorable opportunity for introduction to the profession as the most useful method of attracting the notice of persons interested in such a malformation.

The efforts of the Committee were not crowned with success owing to the high pecuniary consideration which was demanded before even an ocular view of the deformed region could be obtained by the Committee.

The contradictory statements made by the individual led the Committee to doubt the existence of hermaphroditism, and they consider it probably an abnormal or unfinished condition of male development.

Dr. JAMES J. PIERCE described briefly a case of typical hemianesthesia, involving all the special senses, which had developed in a strong, healthy man, as the result of a concussion accident two years before.

Conclusive evidence against malingering was furnished by the fact that the lines bounding the anæsthetic region of the skin and the diminished field of vision were preserved throughout a protracted examination.

No outward sign of disease existed, and the medico-legal value of the symptoms described was obviously great.

DR. EDDES remarked that he had a male patient at the hospital last year who, after a fall with loss of consciousness and temporary hemiplegia, had hemianæsthesia of the most distinct character.

The field of vision was very much diminished on the affected side, and also the color fields, almost as exactly as if the man had studied and remembered Charcot's description of similar cases. Smell, taste, and hearing were diminished on the same side.

#### INFANTILE DIABETES.

DR. WHITE stated that he had recently seen a female child, aged two years and three months, the inner surface of whose vulva, as well as the perineum as far back as the anus, was intensely inflamed, being uniformly excoriated and in parts in a condition of superficial ulceration. Being reminded of similar forms of dermatitis of these parts in adult life, he made inquiry which showed that micturition was too frequent and that the diapers stiffened on drying. Analysis of the urine subsequently made revealed a large percentage of sugar, specific gravity 1012.

The inflamed parts were rapidly improving under black wash and a protecting ointment.

#### SEWAGE IN FARM POND.

DR. BARNES said that in a paper read before this Society in December, 1881, he expressed the opinion that faulty construction of the upper basins of the Sudbury-river system caused the pollution of the water of Farm Pond. A careful inspection of the entire margin enabled him to eliminate sewage as a factor. To-day the conditions are changed at South Framingham, by filling a swamp for railroad purposes, where four years ago a limited amount of sewage was taken care of by the rank vegetation and free exposure on the surface. The increased volume of sewage and the encroachments on the swamp resulted in an offensive odor last summer. To obviate this difficulty a sewer is now being built, and is discharging a stream of filth within about two hundred feet of the gatehouse used to admit water into the city conduit. This spectacle is not only disgusting but is likely to excite serious apprehension, for should an emigrant with cholera chance to stop in the water-closet of the South Framingham station, direct contamination of our water-supply is possible.

DR. H. L. BOWDITCH called the attention of the members of the Section to the fact that a small sum of money had been expended for the purposes of the Section, and moved that some steps be taken to reimburse the Secretary. The Chairman appointed a committee—consisting of Drs. H. L. Bowditch, Frederick C. Shattuck, and Vincent Y. Bowditch—to take the subject into consideration and report a plan for its action at the next meeting.

Adjourned at 10.10 o'clock.

*The Lancet* (May 24) reports a uric-acid calculus without any phosphatic incrustation, weighing fourteen ounces and measuring 14x3½x2½ inches, recently removed by Sir Henry Thompson by the high operation.

#### MAINE MEDICAL ASSOCIATION.

##### FIRST SESSION.

THE Thirty-third Annual Meeting was held in the chamber of the Common Council of the city of Portland, the first session opening at ten o'clock, Tuesday morning, the ninth of June, with the President, Dr. Thomas A. Foster, of Portland, in the chair.

After the ordinary business of a routine character the Treasurer, Dr. A. S. Thayer, of Portland, reported the receipts and expenditures for the past year, and it appeared that a balance of \$717 remained in his hands.

DR. A. J. FULLER, of Bath, one of the visitors to the Medical School of Maine, reported that he had attended a number of the lectures and final examinations, that the School is doing excellent work in educating students and sustaining the standard of the profession, and that it is worthy of the confidence and support of the physicians of the State.

DR. C. R. CRANDALL, of Portland, read a paper on "Abdominal Surgery: Its Growth and Triumphs."

DR. J. M. JONAH, of Eastport, read an essay on the "Diet of Infants," a subject to which he believes too little attention is paid by physicians. In his opinion many mothers injure their babies by nursing them, and, in very many cases, artificial feeding is far preferable to breast-milk.

##### AFTERNOON SESSION.

Delegates from sister societies were introduced as follows: Dr. W. E. Boardman, of Massachusetts, Dr. Edw. B. Frye, of New Hampshire, Dr. H. L. Hammond, of Connecticut, and Dr. Ariel Ballou, of Rhode Island, and were invited to participate in the discussions; and at appropriate times during the meeting several of them took part in the debates, to the pleasure of all their hearers.

The President then read his inaugural address, choosing for his subject: "The Relations of the Profession to other Professions and to the Community at Large." He urged the adoption of a system by means of which all the educated physicians in Maine should be drawn into membership in the Association. Some steps should be taken to prevent the injustice to physicians and injury to the public resulting from the frequent, unauthorized compounding of prescriptions. The removal of the Medical School of Maine from Brunswick to Portland was advocated. Other matters touched upon were expert testimony by physicians; the increase of crime, and the method of diminishing it; and the duty of the profession in regard to alcohol and opium. The address discussed many important problems, and the arguments were enforced by the presentation of statistical tables which Dr. Foster had prepared carefully. Its recommendations were referred to a special committee.

DR. J. A. SPALDING, of Portland, introduced the subject of forming a Maine Physicians' Mutual Aid Association, on the basis of those which have been in operation in New York and elsewhere for many years, and it was referred to a special committee.

DR. B. T. SANBORN, of Augusta, Superintendent

of the Maine Insane Hospital, read a paper on "Acute Melancholia."

Dr. E. H. HILL, of Lewiston, reported a case in which, on account of cancer of the penis requiring amputation, he established a permanent opening in the urethra by an incision through the perineum. The result was most satisfactory.

Dr. S. C. GORDON, of Portland, gave a description of a new operation for the cure of ruptured perineum. The object is not only to shorten the vagina, as in the ordinary procedure, but to diminish its lateral diameter. Silver wire is altogether discarded, and the continuous suture with catgut is employed instead. The pain is much less than when the usual method is pursued, and there is none of the annoyance attending the removal of metallic stitches.

#### EVENING SESSION.

Dr. F. H. GERRISH, of Portland, read a paper on the "Hypodermic Administration of Morphine as a Substitute for Hanging in the Execution of Criminals," taking the ground that, while hanging is often rapid and painless, it is sometimes slow and cruel; and that the medical profession should suggest to the State a method of killing free from objectionable features. A resolution recommending the plan proposed was tabled, on motion of Dr. W. A. Albee, of Camden. Immediately Dr. Albee moved to take the resolution from the table, and, the motion not prevailing, the measure was effectually crushed.

Dr. I. T. DANA, of Portland, made extended remarks on the "Treatment of Bright's Disease," which were followed by a long discussion in which many members participated.

#### WEDNESDAY. — MORNING SESSION.

Telegrams bearing the fraternal greetings of this Association were sent to the State Societies of Massachusetts, Rhode Island, New Jersey, Michigan, and Oregon, who were in session at the same time.

It was voted that the Association hereafter send delegates to the medical societies of the provinces in the Dominion of Canada.

A Nominating Committee was appointed, consisting of Drs. Bates, of Yarmouth, Loughton, of Bangor, J. B. Walker, of Thomaston, M. C. Wedgewood, of Lewiston, A. J. Fuller, of Bath, Hersey, of Oxford, and Hill, of Saco.

Dr. SPALDING, of Portland, Chairman of the Committee on the Formation of a Maine Physicians' Mutual Aid Association, reported that the project was one of too great magnitude to be decided upon before the close of the meeting; and it was, therefore, recommended that the whole subject be referred to a committee with instructions to report in 1886.

Dr. E. E. HOLY, of Portland, presented a report of a first series of one hundred cases of cataract, which he had observed in his practice, and occupied his allotted time with remarks on the natural history and treatment of the disease. An interesting discussion followed, participated in by Drs. Spalding, Weeks, and others.

Dr. A. S. THAYER, of Portland, read a report of a number of cases of acute rheumatism treated with

salicine. These were presented merely as illustrating the method which he had for years found to be the most successful in controlling the disease, and showed very gratifying results. The discussion which followed developed a considerable disagreement as to the value of salicine in this affection.

Dr. C. O. HUNT, Superintendent of the Maine General Hospital, invited the members to visit the Hospital, and particularly to inspect the new amphitheatre and wards.

Dr. H. F. TWITCHELL, of Freeport, read the history of a case of placenta prævia, which possibly may have been caused by a shifting of the location of the placenta, occasioned by a severe jolt. A wide difference of opinion was displayed in the subsequent discussion as to the best method of treating a case of this kind.

#### AFTERNOON SESSION.

Dr. S. H. WEEKS, of Portland, Chairman of the Committee appointed last year to decide the question of inviting the American Medical Association to meet in Portland in 1886, as the guests of the Maine Association, reported that the original committee had enlarged its membership, as authorized, by selecting a new member from each of the sixteen counties of the State. This Committee had issued a circular in August, which was sent to every member, requesting the promise of a contribution to defray the expenses of entertainment. As not a third of the requisite amount had been subscribed by March, the Committee reported to the President and Censors that further action was inexpedient.

The election of officers for the ensuing year resulted as follows: President, Dr. S. Loughton, of Bangor; First Vice-president, Dr. C. G. Adams, of Portland; Second Vice-president, Dr. F. E. Hitchcock, of Rockland; Corresponding Secretary, Dr. J. C. Caldwell, of Buckfield; Publication Committee: the Recording Secretary, *ex-officio*, Drs. C. O. Hunt, of Portland, A. M. Peabody, of Auburn, C. E. Webster, of Portland, and O. St. C. O'Brien, of Bristol; Business Committee: Drs. S. P. Warren, of Portland, and the Recording Secretary; Board of Censors: Dr. G. H. Cummings, of Portland, B. F. Sturgis, of Auburn, E. Adams, of Litchfield, H. E. Hill, of Saco, and A. L. Hersey, of Oxford. Dr. C. D. Smith, of Portland, is Recording Secretary, and Dr. A. S. Thayer, of Portland, Treasurer, each for a term of years.

Dr. S. H. WEEKS, of Portland, made remarks on fractures of the neck of the femur, and showed two specimens which illustrated union by bone after this injury.

Dr. J. O. WENSTER, of Augusta, read a paper on "Local Boards of Health." His conclusions were that a local board should be established in every city and town; that it should be an independent board, and all its members chosen with special reference to their fitness for the work; that the working member or members should receive reasonable compensation; and that necessary health regulations should be adopted as by-laws by the town or city.

Dr. W. A. ALBEE, of Camden, reported a case of retroflexion of the uterus, prolapse of one ovary, and phantom tumor.

Dr. S. C. GORDON, of Portland, reported the

results of a number of cases of Tait's operation. As necrologist, Dr. Gordon reported the deaths of Drs. Eaton, of Wilton, Sturtevant, of Scarborough, Parker, of Ellsworth, Manson, of Pittsfield, Brooks, of Portland, and Harlow, of Auburn.

#### EVENING SESSION.

The annual oration was pronounced by Dr. S. H. Weeks, of Portland, who took for his subject the question, "What can we do to Advance the Medical Profession?" He dwelt with particular emphasis on the necessity for a higher education, and better preliminary training of medical students. Industry and patience were inculcated as essentials to success, even if there be a groundwork of talent.

#### THURSDAY. — MORNING SESSION.

Drs. SMITH, LAUGHTON, and CALDWELL were appointed a Committee on Inter-state Representation.

Dr. F. H. GERRISH, of Portland, chairman of the committee appointed to obtain a State Board of Health, reported that the labors of the committee had been successful, the proposed act passing the Legislature almost without opposition.

Dr. J. O. WEBSTER, of Augusta, reported for the committee appointed to secure a law regulating the practice of medicine, that, as certain defeat would have followed the attempt to press their bill through the Legislature this year, the committee preferred to have it referred to the next Legislature, when it will have a much better chance of success.

Dr. J. M. BATES, of Yarmouth, chairman of the Committee on the Recommendations of the President's Address, reported advising that a special committee be appointed to devise a plan for the prevention of unauthorized refilling of prescriptions by apothecaries; and that the recommendations of the President for increasing the membership of the Association be adopted.

Drs. J. M. Bates, of Yarmouth, G. E. Brickett, of Augusta, and A. J. Fuller, of Bath, were appointed a Committee to Secure the Passage of the Medical-registration Bill.

The Board of Censors reported that the next meeting would be held in Portland, on the first Tuesday in June, 1886. Dr. F. C. Thayer, of Waterville, was appointed orator. Numerous appointments of delegates to various medical societies, and essayists for next year, were made. The delegates to the Massachusetts Society are Drs. F. H. Gerrish and C. D. Smith, of Portland.

The usual votes of thanks were passed to the retiring President; to the city government of Portland for the use of rooms for meeting; and to Dr. I. E. Kimball, chairman of the Business Committee, to whose efficiency so much of the success of the meeting was due.

The Association adjourned before noon.

The attendance at the meetings was unusually great. The enforcement of the rule by which essayists and reporters are limited to twenty minutes contributed very noticeably to the animation and activity of the sessions. The discussions were lively and, in the main, interesting. A good number of new members were admitted, and signs of prosperity appeared on every side. The most marked social features were entertainments on

Wednesday evening, after the oration, by the President at his house in High Street, and by Dr. E. E. Holt at his residence in Congress Street. Both of these were numerous attended, and the guests found in them much pleasure and diversion.

#### NEW HAMPSHIRE MEDICAL SOCIETY.

The Ninety-fifth Annual Meeting of this Society convened in White's Opera House, at Concord, on the sixteenth of June. There was a fair attendance, some 150 members being present at the opening session.

#### THE COUNCIL.

A meeting of the council had been held the previous evening, and applications from seventeen persons were acted upon, all favorably. Two members were retired upon their own application. The request of the officers of the Women's Christian Temperance Union, that the Society would take cognizance of the evils of intemperance, was discussed, and the following resolution was adopted by the council:—

*Resolved*, That the members of the New Hampshire Medical Society fully endorse the position taken by the American Medical Association at St. Paul, in 1882, regarding "the conscientious caution in prescribing alcoholic stimulants," and regard the same to be one of the primary principles of the profession, to which the members of this Society have adhered and always will adhere.

#### PRELIMINARY EDUCATION.

The request of the Medical Society of New Jersey for coöperative measures in an effort to elevate the standard of medical education, was referred to a committee of three who reported that the New Hampshire Medical Society approves of the report of the Medical Society of New Jersey, on "Preliminary Education," and that a committee be chosen to consider the same more fully and report at the next annual meeting. The report was accepted and adopted.

#### STATE EXAMINING BOARD.

The same committee considered the proposition or recommendation of the American Medical Association, made at its last annual meeting, at New Orleans, that each State enact a law to establish a State Board of Medical Examiners and Licensers, and defining the duties of said Board, and reported a recommendation that a committee be appointed by the President to memorialize the Legislature for the passage of such an act in accord with the recommendation of the American Society. The report was adopted.

#### MISCELLANEOUS.

It was voted to pay one half of the legal expenses of the New Hampshire Eclectic Society in defending the celebrated suit of "Doctor" O. C. Gage, and to secure the printing of the decision of the court for free distribution to the Eclectic and Homœopathic Societies of the State.

The resolutions of the superintendents of Ameri-

can institutions for the insane, relative to the immigration of the defective classes, were referred to a committee for investigation and report at some future time.

The Board of Censors reported the granting of twenty-three licenses since the last annual meeting.

#### FIRST DAY.

The meeting was called to order by the President, Dr. JOHN WHEELER, and prayer was offered by Rev. C. B. CRANE, D.D., of Concord.

The usual committees on reception, patients, etc., were appointed.

The following delegates were introduced: Drs. T. A. Foster and E. A. Crandall, of Portland, Maine, from the Maine Medical Society, and Drs. C. C. Pike, of Peabody, and C. C. Odlin, of Melrose, from the Massachusetts Medical Society.

The President then delivered his annual address, his subject being, "Some Professional Relations and Medical Mutations." He dwelt upon the grave personal responsibility assumed by the physician. That of the clergyman is truly grave, but its results are not seen in this world. The laws of the State impose no particular duties upon, or exercise no particular control over, the minister.

The lawyer by his zeal and talent may ascend to the highest places of official trust or emolument, but his responsibility toward his race is also limited, and of opposing counsel only one can be wholly right and only one is expected to be.

Our own profession is more essential than either of these, or both of them, to the present well-being of our race, by its efforts to cure and prevent disease, remedy injury and deformity, and alleviate suffering. Every sense must be alert, the judgment quick and accurate, for the medical man has to decide quickly and often under the most unpropitious circumstances. All hours and all seasons are his times of duty and all classes and conditions are his clients.

The speaker referred to the liability to suits for malpractice to which even the most skillful is liable—a thing the other professions are free from; and spoke of the heroism of the medical profession in the army and navy, in Arctic explorations, and in time of epidemic.

He eulogized the true physician for his freedom from conviction for anything unlawful or unskillful, in spite of the peculiar means within the designing patient's power of misrepresenting his case and of moving jurors by appeals to their sympathies rather than by an array of facts. Theoretically the physician is liable only for want of skill or for negligence; practically he is in danger from the sympathy of the jury; hence another prolific source of personal responsibility not incidental to any other profession; and the partial immunity from fleeing by this means is another tribute to the general skill of the educated physician of our day.

The address suggested certain changes in the law to prevent malignant prosecutions or suits, and a belief was expressed that public opinion as it became more enlightened was already demanding these changes.

Under the second head of the address the speaker gave a history of the profession from its mythical

origin down to recent times, necessarily hurried, referring in its course to the more remarkable discoveries, and after a brief historical account of this Society since 1791, as found in its limited records, closed eloquently by a reference to the great men of the profession in this State who had gone to their reward.

The address was ordered to be printed.

#### MEDICAL SHAMS AND SHADOWS.

an essay by Dr. WILLIAM CHILD, of New Hampton, followed, of which the following is a brief abstract:—

New remedies and methods are not always an improvement on the old. The regular school affords the true foundation for the coming practice, whatever that may be, but there are certain conditions and influences which are harmful to true progress and usefulness. The fallacies in modern practice include, among many others, the number of drugs, the number of remedies for particular diseases, the use of half-secret remedies, absurd credulity of many physicians in new remedies, use of remedies from fashion, fear, pride, or prejudice, great number of specifics, many best remedies abandoned, etc. etc. The speaker declared that disinfectants and antiseptics in their present extensive use constituted a great sham, the *cause* which makes them necessary being too often lost sight of, or allowed to have its way to such extent as to require hogsheads of the articles to do any appreciable good.

The greatest humbug of all, however, is the present condition of practice in diseases of women. The speaker declared that the recently born school of specialists were too much in the habit of finding womb diseases when they did not exist, or when nature was the best doctor. To his attack on modern gynecology, a number of the members objected strongly.

#### EPILEPSY.

Dr. T. B. SAXBORN, of Newport, read a brief paper on "Epilepsy." He believed there was too much use of the bromides, causing, when used to excess, degeneration of the cerebral cells. The bromide of sodium is least objectionable, and particular attention should be paid to the diet, for he had almost always found these patients to be great gourmandizers.

#### GYNÆCOLOGICAL DIAGNOSIS.

Dr. C. B. NICHOLS, of Franklin, read an instructive paper upon this subject, describing the use of the speculum, sound, and bistoury. He referred to the paper read by Dr. Child and dismissed it with a reminder to the author that ridicule was not argument. The speaker dwelt upon the proper positions of the patient while the instruments or appliances were in use, the great necessity of avoidance of exposure, the avoidance of undue haste, and described at length his method of procedure to ascertain and locate the disease. He spoke highly of Emmett's operation for lacerated cervix; lacerations taking place in over thirty-two per cent. of those who have been impregnated.

Dr. HENRY M. FRENCH spoke briefly on nasal catarrh, describing his treatment of it by the use of the Lasser spray, which he considered better than

anything yet brought to the notice of the profession. In answer to inquiries as to his constitutional treatment of this disease, he suggested the use of sponge baths, tonics, and good food. He closed with congratulating his brethren upon the progress of laryngeal study, and upon the fact that the first successful photograph of the larynx was made by an American, it being the one exhibited in Copenhagen at the International Congress by Dr. French, of Brooklyn.

#### REPORT ON SURGERY.

The Report on Surgery, prepared by Dr. G. H. BRIDGEMAN, of Keene, was read, in his enforced absence, by Dr. CHARLES R. WALKER, of Concord.

DR. BRIDGEMAN described the antero-posterior splint adopted somewhat recently, and stated that it was suggested to him, while house surgeon in the Boston City Hospital, by Dr. Goodhue, of New York, who described the method of applying a piece of coarse blanket saturated or dipped in liquid plaster-of-Paris, and the bones held in place while the plaster hardened; this application was to the posterior portion of the leg and the ball of the foot. This he adapts to the anterior aspect of the leg, using gauze or erioline in a sufficient number of thicknesses, and by turning the edges over the pad he had at the first application what was needed, namely, an easy, perfectly fitting, well-padded splint with cushioned edges. For fracture of both bones and the ankle-joint he regarded it as invaluable, in that it will hold the foot at a right angle far more effectively than can be accomplished by side splints, and allow a considerable degree of extension to be made in the foot.

The late Dr. W. D. Robertson, in 1877, invented an appliance which the writer believes has never been described in print, and is thus described: It is peculiarly applicable to those cases of fracture of both bones of the lower leg where a considerable degree of extension may be necessary. A patient who, in July or August, has his leg wedged into a fracture box, with an extension weight added, is about as uncomfortable a mortal at times as can well be imagined. We all remember the comfort afforded patients by the Smith anterior splint, by which the leg is suspended above the bed and allowed free motion from side to side, and the ease to physician and patient with which a compound fracture can be irrigated and dressed after application of this splint. The objection to applying extension by the ordinary method to the limb supported by the Smith anterior is, of course, obvious; the pulley attached to the foot of the bed, being a fixed point, tends to alter the line of bone at the seat of fracture whenever the limb moves in the swinging support. Dr. Robertson obviated this difficulty by the simple device of fastening the pulley to a stout cord stretched taut from floor to ceiling just below the foot of the bed.

An opinion was expressed that the members could not devote an hour to better purpose than by arranging this splint for the next case of fracture of both bones of the lower leg where the fragments tend obstinately to override, and that they would be amply repaid by the comfort afforded.

The following instructing account of a rare injury

noted in medical history—gunshot wound of the knee with perfect recovery of the joint—was given in this report. Reference was made to the tabulated reports from the battlefields and hospitals of the late Civil War, and the fact that Gross declares that in but one case was the limb saved in the Crimea, in none in India, while in the Franco-Prussian and the late Civil Wars, 451 cases of this kind of injury yielded success in only twenty per cent. when treated by excision, and twenty-seven per cent. when treated by amputation. These figures are given to show the gravity of wounds of this part of the body. Now the possibility of complete gunshot wounds of the knee occurring without attendant fracture was for a long time denied, but the army reports furnished a few cases, to which another is added.

Early in September, 1882, the writer was called to see a patient of fifty-two years of age, in Swansey, New Hampshire, who had been accidentally shot by his young nephew, the ball from a thirty-two calibre pocket rifle striking him in the inner aspect of the left knee, just as he was turning and had the joint partially flexed, the parties at the time having been engaged in target-firing. The wound of entrance was found situated about an inch below the lower inside margin of the patella, and on flexing the knee as nearly in the position it was in at the time of the accident as the patient could remember, the puncture appeared to be in a line between the articular surfaces of the bones. The probe entered the joint, but only a slight amount of synovia escaped. Examination of the knee on its outer aspect showed, after some search, a foreign body directly beneath the outer edge of the patella. On removal it proved to be the ball altered to an irregular pyramidal shape from the force of its contact with the structures of the joint. Remembering a wound some years ago from the tine of a pitchfork involving the knee-joint, where recovery was had, it was determined, with much misgiving, however, to treat this as a simple punctured wound of the knee. The battered appearance of the ball increased the hesitation about this course, for the same showed that much resistance had been encountered in its passage through the knee-joint, and indeed there was a groove in the lower edge of the patella where the missile had impinged in its partial exit. However it was decided not to interfere until symptoms demanded it. Constant irrigation of the knee with carbolized water was secured by suspending a pail over it with a candlewick hanging over its edge. During this time the pain and swelling were both moderate, no heat or redness, pulse and temperature normal. The splint was kept on for three weeks and use of the joint gradually allowed. In three months a slight amount of stiffness and weakness of the knee was the only complaint, and this chiefly after overexertion. In six months the knee was practically as sound and well as its fellow for ordinary use.

Numerous authorities tend to prove that at certain flexions of the knee solid bodies can pass in an antero-posterior, and, still more remarkable, in an obliquely lateral, direction through the joint, not only inflicting no fracture, but also scarcely more than grooving the articular surfaces. After a

perusal of several of the above and a note made of several experiments detailed by these authorities, the opinion became confirmed that it had been the rare good luck of this patient to escape serious or lasting injury by the chance of a particular flexion at the time of receiving his wound.

This report also gave an interesting account of ligation of the subclavian artery in its second part; the injury occurring in a woolen-mill where a fragment of the band of a "picker," making 1,200 revolutions a minute, shot off an irregular piece of steel one and one-fourth by three fourths inches and nearly an ounce in weight, which struck the patient three inches to the left and a little above the left nipple, penetrated in an inward and upward direction, tearing through and passing under the pectoralis major and minor, leaving a tract which easily admitted three fingers, pierced the pleura and apex of the lung between the clavicle and first rib, and inflicted a jagged wound in the second portion of the subclavian artery almost directly opposite the point of origin of the superior intercostal artery. Here followed an interesting account of the proceeding in the operation above alluded to. A fatal prognosis was agreed to with but slight reservation, and it proved correct, the patient dying on the third day after the injury. The similarity of this wound to a gunshot wound of the artery led to an examination of the records relating to the subject, which revealed the fact that the first ligation of this artery in its third part was by Sir Astley Cooper, in 1809, and successfully for the first time by Dr. Wright Post, of New York, all previous cases having proved fatal. The artery has been tied on the tracheal side of the sealeni in nineteen cases, all fatal. The artery was tied in second part twice during the Rebellion, both operations being unsuccessful.

Dr. C. R. GIBSON, of Woodsville, followed with a dissertation on Anesthetics, taking strong ground in favor of sulphuric ether, and condemning chloroform. A recent discussion before the London Medical Society has developed the fact that English surgeons were giving up the routine use of the latter. The paper was largely devoted to advice as to the proper, speedy, and comfortable administration of ether. The "tunnel" process was declared against in pointed terms, and the writer urged the necessity of allowing the patient all the pure air desired without forcing him to inhale any part of it the second time, and at the same time of having the air thoroughly saturated with the vapor of ether. This can be done by one thickness of a well-worn napkin or towel wet first with ether and gradually brought to cover the nose and mouth, but kept bagged so as not to come in contact with the skin, then allowing ether to drop slowly upon the cloth, so as to keep wet every point through which air can enter. The one thickness will not perceptibly obstruct the free passage of air to and from the lungs, and in from four to eight minutes the patient will be thoroughly anesthetized, *not asphyxiated*, as is proved by the deep, natural breathing and the perfectly natural color of hands, face, and lips. This method has, in the practice of the writer, *always* been attended with the most gratifying results.

At the evening session Dr. Julia W. Russell read the Report on Obstetrics.

Mention was first made of better results in our city hospitals as to high temperatures, puerperal fevers, etc., in the obstetric wards.

Corrosive sublimate, one to 1000 or one to 2000 is the preferred antiseptic in obstetrics, and its supremacy is due to its powerful and certain action, its almost absolute harmlessness, and its trifling cost.

Recovery of patients after extra-uterine pregnancy is much more common now than formerly, when the treatment was expectant, while now, if a positive diagnosis can be early made, electricity can be used to arrest development and destroy fetal life, when nature usually steps in and effects a cure. Many cases of extra-uterine pregnancy have been reported within the past year. Dr. Thomas reporting the largest number ever seen in his own practice and in consultation. In his reports the death-rate is below one half.

An instance of this kind, with recovery, within the observation of the writer, was given in detail, it being a case of extra-uterine double pregnancy.

#### MELANCHOLIA.

Dr. EDWARD FRENCH, of Concord, read a dissertation on melancholia, detailing the various kinds of the same, and his ideas of the treatment best in such cases. He did not believe in chloral and thought the bromides should be sparingly used. He had found opium alone, or combined with hyoscyamus the best in his practice, but the opium habit and the chloral habit often had to be combated together.

In his practice, in cases when patients had to be forced to take food, the nasal tube had entirely superseded the old esophageal method.

Mechanical restraint is far preferable to chemical. The former is often more painful to friends, but is immeasurably better for the patient. Methods of mechanical restraint are now so perfect as to be in a great measure easy and comfortable to the patient, and the often deleterious effects of the continued use of drugs and potions is avoided.

The writer deprecated the prejudice against asylums, and believed the hospital was the place for all cases of melancholia except the very mildest.

At the beginning of the second day's session on Wednesday, June 17th, three more members were admitted, and considerable routine business was transacted.

A long discussion ensued upon the necessity of increasing the attendance upon the second day of the annual meetings, more than a dozen of the members taking part. The prevailing sentiment seemed to be in favor of limiting papers to fifteen or twenty minutes, with perhaps a similar time to discussions of the same, while it was urged that members who were to deliver dissertations or essays should furnish a synopsis or abstract of the same in advance of the meeting, so that discussion might be more readily had.

#### ELECTION OF OFFICERS.

The Annual Election resulted in the choice of the following Board of Officers for the coming year, the votes in each case being unanimous, except in case

of Vice-president, where there was a slight contest between the friends of Prof. C. P. Frost, of Hanover, and Dr. S. C. Whittier, of Portsmouth: President, George A. Crosby, M.D., Manchester; Vice-president, Prof. C. P. Frost, M.D., Hanover; Treasurer, D. S. Adams, M.D., Manchester; Secretary, G. P. Conn, M.D., Concord; Executive Committee: J. R. Kimball, M.D., Suncook; G. D. Towne, M.D., Manchester; C. R. Walker, M.D., Concord; Board of Censors: President, L. G. Hill, M.D., Dover; Secretary, Geo. Cook, M.D., Concord; Executive Committee: L. G. Hill, M.D., Dover; D. S. Adams, M.D., Manchester; Geo. Cook, M.D., Concord.

The meeting then adjourned to meet at Concord on June 17, 1886.

## THE NEW YORK ACADEMY OF MEDICINE.

STATED meeting May 21, 1885.

DR. T. H. BURCHARD read a paper entitled,

### OBSERVATIONS ON THE TREATMENT, MEDICAL AND SURGICAL, OF ACUTE PERITONITIS.

In peritonitis, the most fatal of all acute inflammatory affections, he believed that the mortality was unnecessarily high. For its rational treatment it was essential to clearly recognize these points: the cause, the natural history, and the natural tendency of the disease. The textbooks gave the causes of death as, first, collapse and, second, asthenia. Clinical observation showed that the following should be recognized: (1) collapse, (2) asthenia (*a*) from cardiac failure, (*b*) from respiratory failure, (3) inflammatory changes in the lungs, (4) hyperpæxia.

A knowledge of the cause in any case was essentially necessary for its satisfactory treatment. All the facts in reference to the disease pointed to the probability that there was no such disease *per se* as peritonitis. Having referred to the alleged difficulties of diagnosis and expressed the opinion that it was possible to make a diagnosis even when the difficulties were apparently very great, he cited certain instances occurring in his own practice to prove the correctness of his position. Sound surgical teachings demanded that we should endeavor to seek out and remove the source of irritation wherever it might be or whatever its nature, and surgical interference was to be made early whenever there was reason to suspect that any abdominal traumatism was giving rise to trouble. In these very halls Dr. Sims had sounded the keynote of the correct treatment.

The peritonæum was exceedingly tolerant of surgical interference, if proper precautions were taken. During the last two or three years a very large number of Tait's operations had been performed with extremely satisfactory results, as a rule; and Tait himself had performed no less than forty laparotomies during commencing peritonitis, in which all the patients had recovered. Dr. Burchard then quoted a large number of operations which he had collected with great care from various sources, and added one of his own to the list. This was a case of omental abscess which he saw

in consultation with the late Dr. F. D. Lente, shortly before the death of the latter, and in which he performed laparotomy with a successful result. An incision was made in the median line from a point one inch below the ensiform cartilage to the umbilicus, under antiseptic precautions. A gallon of warm carbolic water was injected among the matted intestines, and the walls of the abscess were lightly dusted with iodoform; after which two drainage-tubes were placed in position. This case, with the others by different operators which he cited, made forty in all, with twenty-four recoveries, or sixty per cent. of recoveries in a class of otherwise hopeless cases. By way of contrast, he related a fatal case of ulceration of the appendix vermiformis which he saw in consultation. He recognized the fact that perforation had already taken place, and advised immediate operation, but the patient being at that time in comparatively good condition it was refused. Twenty-four hours after he was sent for and asked to operate, but by that time the golden opportunity had passed and the case was hopeless.

The latter part of the paper was devoted to some special points in the medical treatment. Opium had been rightly considered our sheet-anchor in peritonitis, but there were certain conditions in which it could be used only with the greatest caution. Such was the condition of initial collapse, which was dependent on vaso-motor paresis; so that larger doses of opium would be very dangerous in it, though in small quantities it might be used with advantage. Whenever there was danger of cardiac or respiratory failure it was always advisable to give opium or morphia in small doses and in combination with atropia, digitalis, ammonia, or alcohol.

He had found that by far the most accurate and satisfactory method of administering morphia was by hypodermic injection. Atropia was unquestionably the one drug which could be most implicitly relied upon in the treatment of collapse, and it might be given in doses varying from one sixtieth to one tenth of a grain, either alone or in combination with one of the agents just referred to. There was no rule for the quantity of opium to be given in peritonitis. Each case must be a law unto itself. Since adopting the hypodermic method, however, he had been surprised to find how comparatively small an amount was required in a large proportion of cases. In some instances, however, enormous quantities of the drug were called for. Punctures had no effect in controlling inflammation, but were sometimes of service in fulfilling special indications. The external application which was by far the most efficient in this disease was the ice coil, and in this connection he exhibited one made by Messrs. Codman and Shurtleff, which, he said, was the neatest and most convenient apparatus of the kind which he had seen. The cold thus applied was directly efficient by causing reflex contraction of the blood-vessels. Peptonized milk was, as a rule, the best food that a patient suffering from peritonitis could take. In speaking of the treatment of tympanitis he said that pneumatic aspiration of the intestines was neither philosophical nor safe. The insertion of a rubber tube by the rectum was sometimes very

useful in relieving the patient of troublesome gas. Turpentine was to be condemned on account of its irritating effect upon the kidneys, and cases had been noted in which its employment gave rise to albuminuria. In closing, he remarked that the successful treatment of peritonitis involved a personal devotion on the part of the medical attendant which required nothing less than a complete abnegation of self.

## DISCUSSION.

DR. A. L. LOOMIS remarked that he was one of those who did not believe in such a thing as idiopathic peritonitis, and he therefore agreed with Dr. Burchard in the opinion that the first and most important point to be determined was what the exact cause of the trouble was. There were three principal varieties of cases: first, those of the constitutional variety, depending on blood-poisoning of some sort; second, those which resulted from an extension of inflammation from some viscus to its peritoneal covering; and, third, those depending on ulceration of the intestines, with perforation and discharge into the peritoneal cavity, or upon the rupture of an abscess or cyst of some kind. So far as his experience went, he had yet to see a case of recovery when there was unquestionably the presence of gases from the intestines in the peritoneal cavity. It was often very difficult to determine just when the perforation had occurred, and he did not believe that the exact portion of the intestine involved could always be made out. If, however, this could be determined, he heartily agreed with the author of the paper as to the advisability of operating. If he believed that he himself was the subject of ulceration of the vermiform appendix, he did not hesitate to say that he would at once seek out a surgeon who would promptly open the abdomen. In regard to the medical treatment, he thoroughly believed in opium, though with restrictions. Dr. Burchard's point had been well taken, he thought, and he also considered the indiscriminate use of the drug in the early stage of the disease often highly dangerous. Long ago he had adopted the plan of guarding his first doses of opium with atropia. Afterward the matter was not of so much consequence.

DR. R. F. WENT said that the arena of the abdominal cavity was that in which surgeons had been striving most actively during the last ten years. Dr. Loomis had touched the keynote when he said that there was no such thing as idiopathic peritonitis. He would go further than the author of the paper and say that, in his opinion, no patient suffering from peritonitis should be allowed to die without an exploratory incision. Perforation with collapse was the snag on which surgeons were apt to get caught. In a traumatic case they could not tell whether this collapse was due to the entrance of gas into the peritoneal cavity or resulted from hemorrhage. Here came in the value of exploratory incision, and in ninety-four such exploratory incisions Tait had had but three deaths. After the incision had been made it could be decided whether to proceed further or not, according to the condition of affairs discovered.

The President, DR. A. JACONT, said that in peri-

typhlitis there were some cases in which the inflammation remained purely local, while in others, although general peritonitis ensued, the patient recovered; and therefore it was a question of great responsibility whether to operate or not. Very recently he had seen a boy of fifteen who had all the signs of perityphlitis, and although the question of operation naturally presented itself, he had deemed it advisable to wait; the patient in the meanwhile being treated with morphia, atropia, and plenty of ice. The peritonitis afterward became general, but the symptoms were not very urgent, and so again he hesitated to operate, because the general condition was such as to justify waiting a little longer. It was certainly a very difficult question to decide; but he had seen a number of similar cases recover, without operation, as this boy did. He had found that whenever a case of peritonitis became well developed rapidly, the patient had almost invariably had one or more previous attacks. He would be inclined to lay down the rule that when perforation and peritonitis set in very suddenly and the trouble extended rapidly, the operation ought to be performed; but if the process was a slow one, it was advisable to wait.

DR. BURCHARD said that in six cases of typhlitis which he had seen ending fatally, — in five of which he made autopsies, — it was a fact that in every one of them there was a history of one or more preceding attacks. If he saw a patient in collapse, or partial collapse, with a history of previous attacks of typhlitis, he would say that there was a perforation, especially if the individual had recently been suffering from constipation and had taken cathartics freely to get rid of it. The rapidity with which the collapse developed also offered an indication as to whether there was perforation or not.

## Recent Literature.

*How to Drain a House: Practical Information for Householders.* By GEORGE E. WARE, JR., M.Inst., C.E.; Consulting Engineer for Sanitary Drainage (Newport, R. I.). New York: Henry Holt & Co. Pp. 222.

This excellent volume gives the information which every householder, whether in city or in country, should have within his reach. The physician who is alive to the welfare of his patients in regard to the preventable sources of disease, and who ought to have some knowledge of the principles of household hygiene, will here find valuable aid and counsel clearly and concisely stated. The illustrations are simple, and not so numerous as to confuse the reader, the descriptive portions being briefly expressed and devoid of useless technicality of detail.

The principal portion of the book treats of the interior of the house, the arrangement of plumbing, drains, traps, and other numerous appliances necessary to ensure perfect healthfulness and comfort to the occupants. The two closing chapters are devoted to the consideration of the sewage disposal outside the dwelling, and also to the subject of subsurface irrigation.

# Medical and Surgical Journal.

THURSDAY, JUNE 25, 1885.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by CUPPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.

CUPPLES, UPHAM AND COMPANY,

283 WASHINGTON STREET, BOSTON, MASS.

## FERMENTS AND FERMENTATION.

THERE is no doubt that the rôle of the microorganisms in nature is one of great magnitude and importance and that all processes of decomposition, in the non-living products of organization, are largely under their control. While it is undoubtedly true that organized matter is always in a state of unstable equilibrium and ready under the action of incident forces to break up into more simple and stable combinations; that the living state is especially characterized by such destructive changes, though the losses are constantly made good by nutritive assimilation; that somatic death is, under ordinary conditions of warmth, moisture, and access of air, inevitably followed by that molecular and molar disassociation called putrefaction,—it is none the less true that the active agents of all destructive transformations in dead protein matter are microbes; whether these “infinitely little” beings have any part in the normal physiological changes taking place in a healthy body is doubtful.

An idea of the amount of work performed by these scavengers of nature may be gained by reflecting that a grain of yeast may transform more than fifteen times its weight of sugar; the *mycoderma aceti* converts daily into vinegar many hundred times its weight of alcohol; the *aspergillus niger* metamorphoses into gallic acid two thousand times its weight of tannin.<sup>1</sup>

One of the important acquisitions of chemico-biological science is that there is no hard and fast line between fermentation and putrefaction, both processes being incidents in the decomposition of ternary or quaternary substances, as brought about under the influence of similar agencies.

While the bacteria of putrid fermentation are probably of many different species, which have been described with great richness of detail in recent works by Ogston and Rosenbach; some appearing

as microbes in chains (streptococcus), others swarming in putrefying fluids under the grape-bunch form called staphylococcus—*leptothrix*, and *oidium albicans*, and *bacterium termo* being frequent forms: the various kinds of fermentation recognize their specific microphytic causal agents. Among these the best known is certainly the *saccharomyces cerevisiae*, the direct agent of alcoholic fermentation. We are chiefly indebted to Pasteur for first demonstrating (what everybody who has a microscope can now see for himself) that the presence of the torula in a saccharine solution, and the production of certain chemical phenomena, such as the disappearance of sugar and the formation of alcohol carbonic acid and water, are correlative.

While it is, then, a general truth that the breaking-up of saccharine liquids in simpler and stabler compounds is dependent on the action of a definite microorganism, it must be borne in mind that this is not the only way that such transformations may be brought about, for they may be equally well effected by the chemist in his laboratory by means of strong acids. Charles Robin has, moreover, shown that fermentation “is a constant fact in the nutrition of divers vegetables in a unicellular or paneellular state, and even of apples or other fruits in their evolutive period of maturation, and is but a particular instance of nutritive disassimilation with evolution of heat.”

What has been demonstrated with regard to alcoholic fermentation, has also been proved by Gayon (a pupil of Pasteur) with reference to putrefaction; this experimenter having indicated the formation in eggs of the products of the putrefaction of albuminoid matters (lencin and tyrosin) when it was impossible to find in these eggs the least trace of inferior organisms.

It has been of late years taught that the normal fermentations taking place in living bodies are the direct results of the agency of microbes of certain kinds. Thus the transformations effected in foods by saliva, gastric juice, pancreatic juice, etc., are accomplished through *living* rather than *soluble* ferments. This is a favorite view of many living writers, but is, we believe, unsubstantiated. Thus Béchamp has described with great minuteness certain organized ferments found in gastric juice and classed by him as *microzymes*. But Gantier has recently shown in a communication to the Academy of Medicine that these peptic ferments of Béchamp are not organized and are not living things; “they do not proliferate in suitable media; . . . they readily digest albuminoid substances in the presence of the most energetic poisons, such as prussic acid, which destroys all microbes. Moreover, these insoluble corpuscles of the pepsin slowly undergo transformation into a chemical digestive ferment without organization and without life which may be obtained crystallized.”

<sup>1</sup> Van Tieghem.

## THE FATE OF THE MASSACHUSETTS MEDICAL BILL.

THE Bill for Regulating the Practice of Medicine in Massachusetts was defeated in the Legislature on the passage to its third reading by an overwhelming vote. It provided for a board of nine examiners, of whom a minority only could be members of the regular medical profession. The impression seems to have prevailed in certain quarters that this measure was being pushed in some way by the Massachusetts Medical Society. While it is true that a committee was appointed consisting of a few zealous persons who, seeing clearly what the highest interest of the public really demanded, thought it belonged to physicians as conservators of public health to lead in the reform, yet as far as any personal feeling in the matter was concerned it is evident that the sentiment of the great majority of the Society was one of entire indifference. But a small portion thought it worth while to put themselves on record at all. As a matter of fact, the medical profession has much less at stake upon the passage of such a law than the public at large, for neither themselves nor their families are in any danger from unqualified practitioners. It is the non-medical public who are especially concerned in protecting themselves from ignorance and incapacity. The feeling of the physician in the matter should be, and is, no more than that of any other good citizen. In view of the persistent cry of "medical monopoly," which it suits the purpose of charlatanism to raise, it would be better, as we believe, for the medical profession, in order to avoid any possible aspersion of their motives, to stand wholly aloof from any such contest as may come up in the future, and to leave the responsibility for the protection of the public where it belongs, to wit, with the public itself.

## ODIOUS COMPARISONS.

AN English contemporary says a much-needed word regarding the loose and meaningless comparisons often made in medical and surgical writings to describe the size of an object. A favorite standard of comparison is some fruit or other natural product of the country, or else a coin. Now these things convey no definite idea to readers of another nationality. We remember, for instance, in our early student days, trying vainly to get an idea of what was meant by the size of a millet-seed. Our contemporary remarks that, while it was formerly very customary to compare an ulcer in size to a six-penny bit or a half-crown, since the florin has come into more general use ulcers also seem to have become smaller.

So long as one meets only the familiar comparisons of his own locality he is unlikely to realize the objectionable features of this method of description. But the English in their turn are now begin-

ning to be puzzled by the terms they find in the American journals. A description of a tumor as large as a "butternut," or of a slough of the size of a "quarter" (dollar), leaves a foreign reader about where he was before he read it.

We would hardly go so far as to condemn all comparison with natural objects, especially when, as in ante-mortem examinations, definite dimensions cannot be given. A "fetal head" gives a tolerably definite idea of size to the medical mind the world over. A "hen's egg" is of the same average dimensions whether it is produced among the grinding despotisms of the old world or under the free institutions of the new. Perhaps it is as well, when no definite measurement of an object has been possible, to avoid describing it in terms which might seem to imply that an accurate measurement had been made. If an abdominal tumor seem to be about a handbreadth in size, it is as well to say so as to describe it as about ten cm., when the tape-measure in the autopsy-room may show anything from six to sixteen cm.

Figures imply definiteness, and when that is not intended, a universally familiar object may really more accurately give the writer's impression. Nevertheless, the importance should be emphasized of giving definite statements in inches or centimetres, whenever measurements are possible, and of avoiding standards of comparison which are indefinite or of merely local significance.

## THE UNCONTROLLABLE VOMITING OF PREGNANCY.

THE name of Dr. Graily Hewitt, of London, has for several years been identified with that theory of the pernicious vomiting of pregnancy which ascribes this grave condition to flexions of the uterus as their usual cause. Since his first declaration of this view much has been said against it, one of the strongest arguments being that vomiting, in its less aggravated forms, is to be considered almost a normal concomitant of pregnancy. The same condition which causes the "uncontrollable" forms of vomiting must be present to a less extent as the occasion of that degree of vomiting met with in the ordinary cases of pregnancy. But it is unlikely that uterine flexion is present in the great majority of women. That Dr. Hewitt still remains of the same opinion, however, is shown by another paper on the subject, published in the Transactions of the Obstetrical Society of London (vol. xxvi.), and our readers, while not, perhaps, adopting his conclusions, can hardly fail to be interested in the cases cited. These are collected from various sources, and are comprised under two tables, the first consisting of cases wherein the conditions of the body of the uterus were observed and recorded, and the second where abnormal conditions of the

os and cervix only were noted. In the former series, consisting of thirty-two cases, some abnormality was found in the uterus in all but one, sufficient to account, without doubt, for the reflex phenomenon. A great preponderance of the displacements observed were anterior, only some twelve per cent. being posterior.

Impaction of the anteflexed or anteverted uterus within the pelvis was found in twelve of the twenty-three cases of anterior displacement. In only one of the four posterior displacements was the uterus incarcerated in the bony pelvis. In the cases where malposition was not noted other pathological conditions, such as puriform concretions between the uterus and decidua, were found postmortem. The cervix was thickened in six of the cases.

Of eleven deaths, three followed the induction of artificial abortion, seven occurred when no local treatment of the uterine displacement was adopted, and one was quite independent of uterine conditions, there being obstructive disease of the intestines. The twenty recoveries are thus classified: six after artificial abortion, one after natural abortion, seven after manipulative treatment and replacement of uterus, and six following positional treatment, rest, and anti-inflammatory remedies. Dr. Hewitt remarks that in all the cases where attempts were made to raise the uterus from its displaced position, and where the attempt was successful, the vomiting ceased, whereas in the cases where the attempt failed the vomiting continued and the patient died, except when abortion occurred. We observe, however, that nearly as many recoveries took place under "positional treatment," including rest, as under the active manipulative treatment. Moreover, it is a little difficult to distinguish between what is called "no special treatment of the uterus" in the fatal cases and what is described as "positional treatment with rest" in those that recovered. There were no deaths following "positional treatment" of the misplaced uterus, and no recoveries in cases where "no special treatment of the uterus" was adopted; yet we cannot help feeling that it might be difficult for one who did not know how the case was to turn out to decide which treatment was being undergone by a woman lying flat upon her back.

A second table gives a few cases of severe vomiting where the state of the cervix is noted as being hard and unyielding, but where no mention is made as to the existence of displacement of the body of the organ. Of course, these two conditions do not exclude each other. Copeman's treatment, namely, dilatation of the cervix, was practised in most of the cases of rigid cervix, with good results, and we notice no case in which it seems to have induced abortion. Dr. Hewitt, believing the two conditions of uterine flexion and hardness of the cervix to be in many cases concomitant, assumes that the treat-

ment by dilatation owes its success in a measure to the fact that the manipulation which it involves has the accidental effect of liberating an incarcerated uterus. Yet he points out that in one case the vomiting remained unrelieved, although the uterus was in fairly good position, until the rigid cervix had been dilated.

The greater frequency, as shown by the tables, of anterior displacements as a cause of severe vomiting, when compared with posterior ones, is explained by Dr. Hewitt on the ground that in the latter, while the fundus falls back into the cavity of the sacrum, the cervix is tolerably free to move upward to the top of the symphysis pubis, thereby lessening the flexion, even though later impaction, with its characteristic symptoms, may take place; while in anterior displacements the pelvis is not so well adapted for allowing the uterus to expand within its cavity and so readily to get rid of the flexion or tendency thereto.

The treatment recommended, as is the logical result of the views entertained by this writer, all centres upon the restoration of the misplaced uterus to its normal relations. As soon as the malposition has been recognized (and an examination, we are led to believe, will always reveal its existence and its nature), an attempt should be made at redressing the uterus by a proper system of rest. If there is, as is usual, anteflexion or anteversion, the patient should lie on her back; if retroflexion, she should lie prone or semi-prone, with occasional variation to the knee-elbow position. If these methods fail, manual reposition is to be attempted, the hips raised, and a crude pessary or a plain round air-ball pessary inserted. In posterior displacements a Hodge is required, to be removed at about mid-pregnancy.

If these proceedings are unsuccessful, the author advises Copeman's plan of cervical dilatation. Sometimes it can be accomplished by the finger, but often requires a metallic dilator. The author's recommendation of the sponge test in such cases we should regret to see generally followed. The chance that cervical dilatation may amount to an artificial abortion should always be kept in mind, and we believe that its use will be restricted to cases where, if it fail to check the vomiting, an abortion, procured by the additional step, if necessary, of introducing a catheter into the uterine cavity, is the only remaining resource for preserving the patient's life.

We think there can be no question that where marked flexions exist in cases of uncontrollable vomiting, the general plan of treatment advised by Dr. Hewitt is a most sensible one. Whether these malpositions will be found in the proportion of cases that he describes we think exceedingly doubtful.

## MEDICAL NOTES.

—The Secretary of the Treasury has issued the following circular revoking all former orders restricting the importation of rags:—

“Whereas, it has been conclusively shown to the department that, under existing laws, no general regulation can be legally framed whereby the disinfection of old rags can be accomplished in foreign ports to the satisfaction of the several health authorities, therefore it is ordered: (1) That all circulars of this department concerning the disinfection of imported old rags are hereby revoked, and that old rags hereafter imported from foreign countries shall be admitted to entry at the custom-house only upon the production of permits from the health officers at the ports of importation duly authorizing the landing of the same. (2) Vessels carrying old rags arriving at any United States quarantine will be detained by the quarantine officers and held subject to the order of the proper health authorities at the port of destination.”

—Dr. Noël Guéneau de Mussy, an accomplished French physician, has lately died. He was connected by marriage with England, and was a frequent attendant at the meetings of the British Medical Association, of which he was wont to say that it was the greatest professional body in the world. He did much to diffuse among his countrymen a knowledge of medical matters in Great Britain and to foster agreeable relations between professional minds of the two countries.

## NEW YORK.

—At the last meeting of the Society of Medical Jurisprudence, held June 11th, Dr. John C. Peters read a paper on “Some of the Nuisances which Affect the Health and Comfort of Citizens.” Among the sources of such nuisances to which he alluded were oil-factories, gas-works, saw and planing mills, stables and slaughter-houses. Every citizen, he said, was entitled to the protection of the law against every nuisance that rendered life upon his premises uncomfortable or injurious.

—Buddensieck, the proprietor of the row of poorly constructed houses which fell in Sixty-second Street, destroying the life of one of the workmen engaged upon the buildings, has been convicted of manslaughter in the second degree, the penalty for which is confinement in the state-prison for not less than one or more than fifteen years.

—Considerable excitement has been occasioned by the breaking out of two cases of smallpox on Ward's Island among the emigrants who recently arrived on the steamers Weser and Polynesia, which came into port with smallpox on board. The Commissioners of Charities and Correction objected very strongly to the transfer of these passengers from quarantine to Ward's Island, and Dr. A. E. Macdonald, superintendent of the insane asylum on

the island, is reported to have said: “I think that the Emigration Commissioners have done a most disgraceful thing in sending this army of infected immigrants and exposing the wards of the city, as they have done, to the dangers of an epidemic. The portion of Ward's Island allotted to their care was never intended for any such purpose. There have been but about 150 immigrants here at any time of late, and now we have 2,000 of them liable to be struck down with smallpox and other contagious diseases.”

## Miscellany.

## THE LONDON TIMES ON THE MIND-CURE.

WE make room for a few of the comments of the *London Times* on what must perhaps be admitted to be a “Yankee notion,” but is, nevertheless, if we are correctly informed, finding a not uncongenial climate even in old England, as indeed wherever else the “gulls” are gathered together.

“The ‘hub of the universe’ is in the throes of a new birth. It is agitated to its centre by the appearance of a system which we find it hard to classify, since it is at once an art, a science, and a religion. The imperfect apprehension of the old world has sometimes failed to discover the unity, or even the compatibility, of these, but Boston has triumphantly effected their synthesis. Science has always been a rather troublesome element in European speculation, but it is so completely absorbed in the great Boston system that a careless observer might easily fail to discover that it had ever existed. . . . This beautiful discovery naturally sweeps away all the elaborate medical and hygienic nonsense of the profession. We are at once delivered from Koch and Pasteur, and other pestilent fellows who put us in fear of bacilli, and go about to have us inoculated with their nasty attenuations. The other class of nuisances who wag their heads solemnly at all the savory meats that our soul loveth, and mutter ‘gout’ when we bid them pass the port, are also put entirely out of court. When a healer can produce a chemical change in the fluids of the system he can, of course, render it tolerant of whatever the patient may fancy—can convert lobster salad into a tonic, and make alcohol, in its various seductive forms, as innocent as water. There are varieties of treatment and method in the new sect. One lady holds healing-power to be inseparable from Universalism, whatever that may be. Another insists that the minds of her patients must be entirely free from guile, and to effect their purification she makes them confess all their shortcomings. Her practice is likely to be amusing. Some use ‘will power,’ others simply ‘let the truth work through them.’ One lady practitioner sitting in Boston has cured a friend in Sacramento of inflammatory rheumatism, and another bridges distance by putting a doll in the chair in front of her to represent her absent patient. A very curious thing is that, although nothing evil exists and poisons operate only through the fears of the

patient, Mrs. Eddy, the head of the Christian Scientist section, holds that her husband was murdered by another Scientist, who 'thought arsenic into him.' This is really very alarming, and will reduce, in many people's eyes, the value of the new system. If the contemplation of truth and wisdom can be used to think arsenic into us, probably in a form which will entirely baffle existing medical jurisprudence, it is easy to understand why the Boston press deal gently with the new sect. Even a fighting editor is no protection against this sort of thing. The outraged Christian Scientist sits down for twenty minutes in her own room and 'thinks arsenic' at a doll representing the scoffer, who forthwith dies of 'hereditary fear.' Our correspondent tells us that the new system has not yet fallen into the hands of the 'scalawags.' Though we have no idea who they are, we are heartily glad to hear it, since from their name we should suspect that they are capable of *de tout*. Rev. A. J. Gordon, D.D., a prominent Baptist clergyman, has examined the creed of the Christian Scientists, and pronounces it a mixture of Pantheism and Buddhism. He also says it is a 'witches' cauldron.' Perhaps he knows what he means, but we fear that his analysis will not add much to our knowledge on this side of the Atlantic. We have got Pantheists and Buddhists among ourselves, and anybody who wants to enjoy temporary delirium cannot do better than listen for half an hour to the apostles of either. When they are mixed up together in a witches' cauldron the result must be something too chaotic for the human reason to grapple with. Hundreds of young ladies are attracted to the new sect under the impression that they are getting a finer form of Christianity. On the whole, we are disposed to agree with Dr. Gordon in his belief that 'this is not the final issue.' In America, especially, these hysterical quasi-religious absurdities are usually intimately connected with tendencies of a far from admirable kind. The saying that extremes meet is never more true than when one of the extremes is transcendental rubbish of the kind that seems to have captivated the good people of Boston."

### Correspondence.

#### IMPRISONMENT OF MEMBERS OF THE MASSACHUSETTS MEDICAL SOCIETY.

LAWRENCE, MASS., June 20, 1885.

*Mr. Editor.*—Will the Committee of Arrangements for the late annual meeting of the Massachusetts Medical Society have the kindness to inform the hundred or more luckless Fellows, who were imprisoned in the hall of the building in which the exercises were held, while the line of march to the banquet (?) building was forming, and who were refused egress until most of their more fortunate brethren had left the hall above, by authority of what law or precedent or canon of courtesy they exercised such extraordinary powers?

During a membership of nearly a third of a century, the writer recalls no other occasion on which such an affront was cast upon the Fellows of the Society.

If it sometimes happen that physicians are prevented by professional or other duties from reaching the place of meeting until after twelve o'clock, whereby they are denied the privilege of listening to the annual

address, is it meet that they be still further punished by being adroitly decoyed into a convenient *en-de-sac* and there herded like so many outlaws, guarded by a rope and a line of sentinels, until the Chairman of the Committee of Arrangements, or some one else having a little 'brief authority,' shall signify his pleasure to restore them their liberty?

Surely, in the future, such a ridiculous precedent will be "more honored in the breach than in the observance" of it.

ONE OF THE IMPRISONED.

#### AD UNCIAS.

MARCH 20, 1885.

*Mr. Editor.*—In writing prescriptions, one often finds it convenient to end off as follows:—

Aque, ad 3 iv ;  
or, aque, q. s. ad 3 iv ;  
or, aque, q. s. ut ft. 3 iv.

Having had some doubt as to the classical correctness of these formula, or at least of the first two, I addressed a letter the other day to Prof. George M. Lane, of Harvard College, who referred the matter to a pupil, Mr. Morris H. Morgan, and has sent me an interesting reply containing the result of Mr. Morgan's investigations and his own indorsement. Mr. Morgan finds each of the forms above given to be correct, and gives the following examples from classical writers to prove it.

In the work "*De Re Culinaris*," said to be written by the noted epicure Apicius, is a receipt for mullet sauce, part of which is as follows:—

"*Concinna tantum quantum quinque digitis tollis piperis ad dimidium ejus.*"—Apicius ix, 13.  
"*Adem Junoni ad partem dimidiam detegit.*"—Livy 42, 3, 2.  
"*Quasi ad talenta quindecim coegit.*"—Ter. I, 1, 93.  
"*Terna ingendo hincque egress etc ad perennes sufficit amplex.*"—Livy 4, 30.  
"*Ad quod et ceteros non suffecerint.*"—Quint. 12, 1, 12.

The examples of *ut* with the subjunctive are of course numerous and need not be quoted.

The question is certainly more curious than important, but not without interest to those who like to write correctly.

Yours respectfully,  
EDWARD T. WILLIAMS, M.D.

[Owing to the intervention of a holiday (June 17th) in the routine of the printing-office, this letter, which we published last week, escaped editorial revision, and was considerably mangled by the compositor. This was especially unfortunate as the letter is in the interest of correct writing. We therefore republish it in its proper form.—Ed.]

#### SUMMER REGISTRY OF PHYSICIANS.

BOSTON, June 18, 1885.

*Mr. Editor.*—In the JOURNAL of the 11th inst. it was announced that members of the Suffolk District Medical Society might send their names, addresses, and the days and hours when they could be found during the summer, to the Boston Medical Library, and that, upon the receipt of a sufficient number of names, public notice would be given in the *Advertiser* and *Transcript*, as was done last year. As some misunderstanding of the purport and significance of this notice seems to exist, we have been requested to state that it was never intended that any names should be published, merely that the public should be informed of the fact (see papers of last year) that, where they had previously sought nurses only, they might, during the summer, seek physicians as well, if their regular attendant was absent upon his vacation.

Of course, if a "sufficient number of names" was not received to make the plan advantageous to the

public, it would be of no use to notify said public of the existence of such a plan.

Facts warrant us in believing that there exists a demand for a summer registry of physicians for the protection of people who, for any reason, are detained in the city during the summer. To avoid making invidious distinctions, when asked for the names of physicians attainable during the summer months, it seemed best to inaugurate a registry and to thus allow individuals to make their own selections.

Very respectfully,

EDWARD WIGGLESWORTH, M.D.,

FREDERICK I. KNIGHT, M.D.,

Subcommittee Boston Medical Library Association.

## POOR FOOD AT THE MASSACHUSETTS MEDICAL SOCIETY DINNER.

*Mr. Editor.*—The task of any Committee of Arrangements is apt to be a thankless one; and often their best endeavors fail to give satisfaction. There is good reason for complaint of the dinner at the Massachusetts Medical Society this year, although your correspondent of last week is wrong, I think, in attributing it to the quality of the food, which was as good as

the funds at the disposal of the committee allowed, and differed in no respect from that of the last few years, except in being better.

The service and the quantity of the food are just causes for complaint. The reason is that there was an unusually large attendance at the dinner this year, larger than the committee had any reason to expect; there being 775 tickets sold, a number greatly in excess of previous years, and a very much larger number than usual. About 125 were sold during the hour immediately preceding the dinner: too late to make the necessary arrangements for increase of service and food. We are obliged to give a guaranty for a number of plates, not less than fifty in number, of those who are to be fed; and with the amount of money appropriated for the expenses of the dinner, the committee are obliged to exercise strict economy. If the attendance had not been so exceptionally large, I do not think there would have been any cause for complaint. If in the future members will try to purchase their dinner-tickets early in the day instead of at the very last moment, it will enable the committee to meet any unexpected draught on the resources of the caterer.

H. C. HAVEN, M.D.,

Chairman Committee of Arrangements.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JUNE 13, 1885, TO JUNE 19, 1885.

PORTER, J. Y., captain and assistant surgeon. Having been found incapacitated for active service by an Army Retiring Board, ordered to proceed to his home and report by letter to the Adjutant General of the Army, S. O. 136, A. G. O., June 15, 1885.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY, DURING THE WEEK ENDING JUNE 20, 1885.

ARTHUR, GEORGE, passed assistant surgeon. Granted leave of absence for one year, with permission to leave the United States.

DEANE, C. W., passed assistant surgeon. Granted leave of absence for three months.

CLEBORNE, C. J., medical inspector. As member of Medical and Naval Examining Boards, Philadelphia, Pa., June 22, 1885.

LIPPINCOTT, GEORGE C., passed assistant surgeon. Detached from temporary duty, Naval Academy, and waiting orders.

MACRUE, BENJAMIN S., surgeon. As member of Medical and Naval Examining Boards, Philadelphia, Pa., June 22, 1885.

SHAYER, JOSEPH. Commissioned an assistant surgeon, active list, June 12, 1885.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE WEEK ENDING JUNE 13, 1885.

WYMAN, WALTER, surgeon. To proceed to New York, N. Y., and assume charge of the service, relieving Surgeon Sawtelle, June 8, 1885.

BANKS, C. E., passed assistant surgeon. Granted leave of absence for thirty days. June 12, 1885.

#### ERRATA.

IN the report of the annual meeting of the Massachusetts Medical Society, June 18th, p. 602, the record should be that the proposition of the Nebraska State Medical Society for the appointment of an inter-state medical representation was laid upon the table.

IN the report of the Boston Society for Medical Improvement, June 18th, page 608, the question of Dr. Lyman, and the reply of Dr. Greenough, in regard to the distinction between nervous symptoms and cerebral syphilis should have been placed in connection with the remainder of the discussion on Dr. Greenough's paper.

#### BOOKS AND PAMPHLETS RECEIVED.

Face and Foot Deformities. By Frederick Churchill, C.M., surgeon to the Victoria Hospital for Children. With illustrations of new appliances for the cure of Bunion, Club-foot, etc. Philadelphia: P. Blakiston, Son & Co., 1885.

Shall we hang the Insane who commit Homicides? By Clark Bell, Esq., of New York. (Reprint from the Medico-Legal Journal.)

A Practical Treatise on Urinary and Renal Diseases, including Urinary Deposits. Illustrated by numerous cases and engravings. By William Roberts, M.D., F.R.S., assisted by Robert Maguire, M.D., Lond. Fourth edition. Philadelphia: Lea Brothers & Co., 1885.

Fifth Annual Report of the Thomas Wilson Sanitarium for Children of Baltimore City. 1885.

Four Cases of Alexander's Operation of shortening the Round Ligaments of the Uterus for Retroversion. By Paul F. Munné, M.D., of New York. (Reprint from New England Medical Monthly, May, 1885.)

Bacterial Pathology. A Series of Papers on the Exhibits at the Biological Laboratory of the Health Exhibition. Illustrated. (Reprint.) New York: The Industrial Publication Society, 1885.

A System of Practical Medicine by American Authors. Edited by William Pepper, M.D., LL.D., assisted by Louis Starr, M.D., etc., etc. Volume II. General Diseases continued and Diseases of the Digestive System. Philadelphia: Lea Brothers & Co., 1885.

The Presalbuminuric Stage of Chronic Bright's Disease. By Charles W. Purdy, M.D. Chicago. 1885.

## INDEX TO VOLUME CXIII.

- Abdominal surgery.** Ten cases of abdominal sepsis, Fox, L. S., 76; what becomes of intra-peritoneal ligatures? Irish, H., 318; Two rare cases of abdominal surgery, Howard, W. A., 342.
- Abortion.** Treatment of abortion with cases, Sullivan, J. L., 222, 223.
- Abscess.** Two cases of retro-pharyngeal abscess, DeBois, T. A., 53, 62; syphilitic abscess and necrosis of the tibia, Beates, H., 239; Pus cells and peritonitis: their pathology and differential diagnosis, Gibson, J., 317.
- Acclimatization.** Virchow, R., 402.
- Acne.** Some etiological factors in the acneiform diseases, Fell, 542.
- Adams, S. E.** Against the wet-nurse, 380.
- Age.** The influence of age on the development of disease, 69.
- Agnew, C. R.** Operation for removal of dislocated crystalline lens, 107.
- Albumen.** Ferrocyanide test pellets for albumen, Pary, 157.
- Alcoholism.** Chronic alcoholism, 556; Two chronic and fifty attacks on drunkards, illustrating the most prominent lesions of chronic alcoholism, Fornad, 549.
- Alimentation in laryngeal phthisis.** Robinson, R., 59.
- Alimentum.** The galvanic anastomosis in laryngological practice, 58.
- Ambulance Corps.** 123.
- American Public Health Association.** 398.
- Amory, R.** Electrolysis and its therapeutic applications, 529, 534.
- Anæsthesia.** Another investigation of the discovery of anæsthesia, 91.
- Anæsthetics in normal labor.** Kingman, R. A., 337, 347.
- Analgesics.** On new analgesic medicaments, Dujardin-Beaumez, 272.
- Anatomy.** On a seldom-described artery, arteria terminalis, with suggestions as to the names of the principal cœnebralic arteries, Wiggers, B. G., 16; on two little-known cerebral diseases, with suggestions as to their nomenclature, Robinson, R., 67, 17; anatomical nomenclature, 65; the study of anatomy, Moss, G. H., 101; anatomy at the Harvard Medical School, Dwight, T. J., 143; recent progress in anatomy, Dwight, T. J., 271.
- Andersson, J. A.** Treatment of paratubercular conjunctivitis, 108; olive oil as a medium for dissolving cocaine for application to the eye, 121; contagious conjunctivitis: its cause, prevention and treatment, 260.
- Anæurism.** Gastric anæurism, Gerry, E. P., 199.
- Anus.** Meddens, MDCCCXXXV, 652.
- Antipyretics.** 108.
- Antisepsis.** 108.
- Antiseptic Surgery.** The application of antiseptic principles to genito-urinary surgery, Cabot, A. C., 245; antiseptic surgery at the Boston City Hospital, Bullis, W. P., 417; antiseptic surgery in anatomy, 436.
- Antiseptic treatment of the surgeon-general of the United States Army.** 598.
- Aspiration of the aorta.** 629.
- Ataxia.** Locomotor ataxia: anisotropic lateral sclerosis: lateral sclerosis, 629.
- Ayer, J. B.** Cases of glycosuria, 393, 397; points of interest connected with an epidemic of scarlet fever, 587.
- Bacillus.** Finkler and Priore's bacillus, 161; the specific anti-infective, 161; the bacillus of the human eye, 161; the bacilli of tuberculosis and those of malignant pustule (anthrax), Cushing, E. W., 652; a case of phthisis with mucous bacilli: complete arrest of the disease, Bowditch, V. Y., 558, 560.
- Bacteriology.** The bacteriology of the human organism in health and in disease, 18; micro-organisms and their relation to disease, Nelson, S. N., 470; observations on the relation of bacteria to certain purulent inflammations, Cushing, E. W., 471.
- Baker, W. J.** On the human eye-system, 195, 245; case of total extirpation of the uterus for cancer, 155, 179.
- Bang.** On tubercular milk, 177.
- Baudry (St. Louis).** Notes on hydrochlorate of cocaine, 17.
- Baylor, H. C.** On the chicken, its history, its uses, and its diseases, 108.
- Belk, C. R.** Dr. Elliot's attack on the Massachusetts medical exam. net system, 136.
- Bellefleur Hospital.** The comparative recorded operations in Bellefleur Hospital, 181.
- Bibliography.** Albert, T. C., clinical lectures on venereal diseases, 106; Ashurst, J., the principles and practice of surgery, 141; Bair, T., main mal of diseases of the ear, for the use of students and practitioners of medicine, 625; Baugh, E., children, its history, its uses, and its diseases, 102; Baugh, E., manipulation of the microscope, 152; Behrens, J. W., the microscope in botany: a guide for the microscopical investigations of vegetable substances, 235; Bugbee, H. R., Berlin as a medical center, 108; Bullis, W. P., text-book of anatomy, 108; Burroughs, E. J., practical therapeutics, 65; Clark, J. R., the ten laws of health, or how diseases are produced and prevented, and family guide to protection against epidemic diseases and other dangerous ailments, 108; Burt, F., text-book of practical medical chemistry, 509; Bruntin, T., Lauder, a text-book of phar-
- macology, therapeutics and materia medica, 504; Burnett, C. H., the ear, its anatomy, physiology and disease: a practical treatise for the use of medical students and practitioners, 205; Butler, R. T., diseases of the tongue, 625; Cheyne, W. W., antiseptic treatment of the wounds, 108; Child, E. J., the science and art of surgery, 593; Cripps, H., diseases of the rectum and anus, including a portion of the Jacksonian prize-essay on cancer, 549; Doley, C. S., the treatment of bacteria investigations, 553; Dujardin-Beaumez, 272; Edwards, J. F., modern therapeutics of the diseases of children, with observations on the hygiene of infancy, 17; Fowens's manual of chemistry, theoretical and practical, 556; Gowers, W. R., lectures on the diagnosis of the diseases of the nervous system, University College lecture, 624; Gynecological Society, American, transactions, IX, 473; Haddad, A. H., the inhalation treatment of the diseases of the organs of respiration, including consumption, 108; Haddad, A. H., the treatment of the diseases of the organs of disease, 545; Jacond, S., the curability and treatment of pulmonary phthisis, 181; James, P., laryngoscopy and rhinoscopy in the diagnosis and treatment of diseases of the throat and nose, 332; Kélik, P., a guide to the study of the anatomy and treatment of diseases of the rectum and anus, 352; Leonard, C. - Chicago.** Letter from Chicago, 286.
- Children.** The prophylactic treatment of ophthalmia neonatorum, Mantou, W. P., 131; the convulsions and gavage, 243; report on diseases of children, Rotch, T. M., 581.
- Cholera.** Dr. Ferri and his methods, 115; copper and cholera, Peters, E. D., 118; deaths from cholera in Philadelphia, 118.
- Circulatory System.** The treatment of the changes in arterial pressure, with suggestions as to the names of the principal encyclopaedic arteries, Wilder, B. G., 16; the treatment of hemorrhoids by injection, Kelsey, C. B., 36; a comparison of the changes in arterial pressure after ligature in the arteries arteriosus and umbilical arteries after birth, Warren, J. C., 513; gastric aneurism, Gerry, E. P., 199; a case of peripartur pulmonary embolism, Fish, S. A., 201; recent progress in thoracic diseases, Snodgrass, G. C., 202; changes in the blood-supply of the brain, Webster, S. G., 47; inclusion of the pericardium in pericarditis, Mikhailov, A. E., 297; a rare malformation of the heart, Brower, G. E., 311; obscure cases of weak heart, Santovito, R. van, 250; a new cardiac tone, 509; aspiration of the aorta, 629.
- Cirrhosis.** Uniform cirrhosis of both lungs, McCollum, W., 420.
- Clark, S. T.** Psoriasis and peripostitis: their pathology and differential diagnosis, 517.
- Climate.** Even divisions of climate based upon combined atmospheric humidities, Denison, C., 16; the climatic treatment of phthisis, Williams, H., 313; the climatic treatment of disease, with an illustration of Western North Carolina as a health resort, Marx, H. O., 118; the climatic treatment of phthisis, Denison, C., 178.
- Coal Gas.** The dangers from coal gas, 229.
- Coca.** The mode of cultivation of coca, 156.
- Cocaine.** Cocaine in cracked nipples, Meunier, G. C., 231; cocaine in senile senescence, 334; cocaine for teething, Wigglesworth, E., 478; Cocaine in dentition, Forster, E. J., 532.
- Coggins, D.** A case of erysipelas, 415.
- Coleman, J. J., and Nickerson, Prof.** Effects of very low temperatures on living organisms, 324.
- Colic.** Cholera and pulmonary colic, Tait, 309.
- Colles' Fracture.** Treatment of Colles' fracture by a new method, Keene, G. F., 122.
- Collins, J.** Treatment of carbuncle, 447.
- Colman, J. J.** Congenital malformation of colon, Naudede, C. B., 417.
- Conjunctivitis.** Contagious conjunctivitis: its cause, prevention and treatment, Andrews, J. A., 296.
- Connor, P. S.** Vessel explorations, 36.
- Concomitant Marriages:** their effect upon oil-spring, Withington, J. F., 472.
- Contagious Diseases.** A note from the Boston Board of Health, concerning contagious diseases, 662; shall physicians report contagious diseases, 7548.
- Corbett, W. T.** Progress of the skin of reflex nervous causation, 25.
- Coryza.** Suggestions in regard to the causation and treatment of coryza, Flint, A., 419.
- Covance and Covage.** 414.
- Cremation in the military service,** Marble, J. O., 157.
- Cushing, L. W.** Medical study in Germany, 215; observation on the relation of bacteria to certain parts of the intestines, 1; the specific and infectious character of tuberculosis, with exhibition of the bacilli of tuberculosis, and those of malignant pustule (anthrax), Cushing, L. W., 553.
- Cutaneous System.** Periodical change of color of the hair, 22; diseases of the skin of reflex nervous causation; Corbett, W. T., 25; vitiligo, Reed, R. H., 36; leucophaea buccalis et lingue, or ichthyosis lingue, successfully treated by the galvanic-cautery, Ingalls, E. F., 283; a case of Melano-sarcoma of the nose, caused by galvanic-cauterization, Lincoln, R. P., 58; the pathogenesis of certain affections of the skin, Tilden, G. H., 33; the treatment of the port wine marks by electrolysis, Hardaway, W. A., 231; tumors on root-point in the etiology of psoriasis, Sherwell, S., 231; dysidrosis, Fox, G. H., 234; mycological studies in tinea favus and tinea trichophyina, Robinson, A. R., 253; on the structure of the derma and its relation to the growth of the epidermis, Hertzman, C., 253; case of tuberculo-epithelioma of the middle of hereditary origin, Hardaway, W. A., 230; clinical notes on psoriasis, Greenough, F. B., 231; cases of angina pigmentosum et atrophicum, White, J. C., 233; relation of lupus vulgaris to tuberculosis, Rydick, J. N., 233; necrosis fungoides, Tilden, G. H., 235; urethral irritation in the male as a cause of certain neuritis and of acne, Denslow, L. N., 256; on syphilitic infection, Taylor, R. W., 257; observations on the oleates, Stollwaggon, H. W., 257; a case of syphilitic aphasia and paraplegia followed by death, with an account of the autopsy, Denslow, L. N., 258; remarks on electrolysis and other practical topics, Hertzman, C., 256; a case of multiple myomatosis of the skin accompanied with psoriasis, Hardaway, W. A., 254; an unusual case of tylosis on the hands, Morrison, E. B., 254; the relations of herpes herpetiformis and certain other forms of disease to dermatitis herpetiformis, Dühring, L. A., 255; "pidermises," 252; cases of secondary syphilis, Boma, J. G., 253; scrofula and necrosis fungoides, Tilden, G. H., 284; report on dermatology, Tilden, G. H., 438; is craniotomy upon the living fetus ever justifiable? Dixon, R. B., 265, 278.
- Dana, J. T.** The treatment of chronic Bright's disease, 292.
- Dandrige, N. P.** Clinical notes on osteotomy, with report of cases, 25.
- Danvers Lunatic Hospital.** Overcrowding at Danvers lunatic hospital, Peters, E., 119.
- Daturine.** The antidote of Daturine, 324.
- Davenport, F. H.** Some forms of dyschorrhea, and their treatment, 249; report of progress in gynecology, 273; post-partum hemorrhage, 298; dilatation of the uterus: a consideration of some of the methods and their value, 643, 645.
- DeBolt, T. H.** Two cases of retro-pharyngeal abscess, 53, 62; the rapid fatality of tuberculosis when involving the pharynx, 337.
- Delavan, C. B.** Erysipelas of the larynx and pharynx, 40.
- Denison, C.** The even divisions of climate based upon combined atmospheric humidities, 16; the climatic treatment of phthisis, 478.
- Dennis, F. S.** Fracture of the patella, with illustrative cases, 421.
- Denslow, L. N.** Urethral irritation in the male as a cause of certain neuritis and of acne, 256; a case of syphilitic aphasia and paraplegia followed by death, with an account of the autopsy, 258.
- Denslow, L. N.** Case of early syphilitic cephalalgia followed by aphasia, paraplegia and death, with an account of the autopsy, 415.
- DePitts, C.** Cocaine for teething, Wigglesworth, E., 478; cocaine for dentition, Forster, E. J., 532.
- Derby, H.** Two cases of penetration of the eye-ball with scissors in the operation of strabismus, 110; on the abuses connected with gratuitous medical treatment, 110; on the abuses connected with gratuitous medical treatment, 110; the treatment of strabismus by the Italian method, 111; contagious ophthalmia in some of the orphan asylums and residential schools of New York city, 125.
- Dermatology.** Report on dermatology, Tilden, G. H., 438.
- Diabetes.** Uses of glycerin, Ayer, J. B., 393, 397.
- Diarrhoea.** The treatment of some forms of diarrhoea, 307.
- Didman, H. D.** Tubercular consumption: is it ever hereditary? 547.
- Dietetics.** The study of dietetics, 183.
- Digestive System.** An enormous gallstone, Livingstone, 21; the use of galvanism in chronic diseases of the pharynx, Shirley, 37; leucophaea buccalis et lingue, or ichthyosis lingue, successfully treated by the galvanic-cautery, Ingalls, E. F., 283; two cases of abdominal section, Fox, L. S., 56; the treatment of hemorrhoids by injection, Kelsey, C. B., 36; persistent flatness over the liver as proof that acute diffuse peritonitis is not associated with intestinal or gastric perforation, with a description of the intestines, with the report of a case, Wood, C. S., 169; a method of direct local treatment for diseases in the region of the ileo-cæcal valve, and also for the safe removal of impactions of the intestines, Leale, G. A., 169; gastrostomy in Leiden, 215; case of laparotomy, Hamilton, H. J., 241; successful case of laparotomy for intestinal obstruction, Hrad, J. B., 221; a rare case of intestinal malformation, Hurd, E. P., 291; the treatment of some forms of diarrhoea, 307; jaundice, 309; laparotomy for intestinal obstruction in an adult, Tripp, F. S., 413; congenital malformation of colon, Naudede, C. B., 417; cocaine for teething, Wigglesworth, E., 478; cocaine in dentition, Forster, E. J., 532; strangulated umbilical hernia, 622; two cases of tubercular intestinal ulcerations and general tuberculosis, Whittier, E. M., 583; cases of abdominal disease with obscure diagnosis, Naudede, C. B., 416; fissure of the anus following parturition, Mhoir, F., 651.
- Diphtheria.** Two cases of diphtheria, Carrington, H. J., 326.
- Disinfection.** How shall the practitioner disinfect his hands? 733.
- Dislocations.** Recurring luxations, Moore, K. N., 510.
- Dispensary.** Report of the Boston Dispensary, 229.
- Dixon, R. B.** Is craniotomy upon the living fetus ever justifiable? 265, 278.
- Dock, D. C.** Case of secondary epithelioma, 223.
- Dor, O. W.** A case of so-called uncontrollable vomiting of pregnancy, 498.
